# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as the outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

- AUTOMATIC** interchange of up to 4 sample and 4 reference cells
- AUTOMATIC** re-cycling over any preselected wavelength range
- AUTOMATIC** recordings at predetermined time intervals.

Please send for descriptive brochure

*Save operator time, increase speed and efficiency with Unicam automation for:*

ENZYME REACTION RATES

LIQUID COLUMN CHROMATOGRAPHY

ALL ROUTINE ULTRAVIOLET AND  
VISIBLE SPECTROSCOPY

# HENDREY SPARK RECORDER Type 1487A

Compact and weatherproof, this single channel recorder is light in weight and easily portable. The Perspex window gives a clear view of the heat-sensitive chart for approximately 6 in. of its length.

The instrument can also be used mounted on bench, wall or panel and is supplied with mounting plate incorporating three anti-vibration mountings which render the instrument shock-proof and vibration-proof to service standards.

An electro-magnetically operated stylus, operated by a separate switch not supplied with the recorder, provides transverse markings near the edge of the chart. Provision is made for an external alarm circuit which can be pre-set to operate at any deflection from zero to full scale by means of a control on the case.

*Sensitivity—50 micro-amps. Full scale. Supply—12 Volt, D.C.*

## REPLANNING BRITAIN'S SCIENCE AND TECHNOLOGY

THE anniversary address which Sir Howard Florey delivered to the Royal Society on November 30 (*Nature*, 204, 1129; 1964) is of outstanding interest on two counts, both of which have a direct bearing on the present proposals of the Government in respect of science and technology. First, Sir Howard, in announcing the Society's decision to increase the number of annual elections to the Fellowship from 25 to 32, intimated that it was proposed to work out procedure for ensuring that a large proportion of future elections should comprise Fellows whose distinction lay in the applied sciences, both on the biological and physical sciences, and with some consideration too of disciplines at present inadequately represented or not at all. Sir Howard made it clear that this step was being taken deliberately to demonstrate the interest of the Society in technology and all that it meant to the Nation.

As a means of enhancing the prestige of technology and the technologist this step should be far more effective than the establishment of a separate Royal Society of Technologists, as was advocated, for example, by Sir Gordon Sutherland. Moreover, the Royal Society is taking other steps which should assist to that end. Lectures on applied science are to be given in 1965 and 1966 particularly for the information of the Fellows, and a conference for headmasters and others interested in education is being arranged in conjunction with the Engineering Institutions Joint Council with the view of letting it be known, as widely as possible, that the applied sciences offer just as splendid careers as the so-called 'basic sciences'. Taken with such forthright addresses as those given recently by Prof. I. D. Rattee (*Nature*, 204, 1017; 1964) and Vice-Admiral Sir Frank Mason (*Nature*, 205, 2; 1965), such measures should make an invaluable contribution towards the removal of the false idea that applied science is in any way inferior as an intellectual effort to pure science, though it may be a slower task to remove the attached social disadvantage.

That, however, should be assisted by the increasing relations between Government and science, to which Sir Howard Florey next referred, at least if those relations are wisely elaborated with clear ideas, on one hand, as to the nature of politics itself and, on the other, as to what is involved in science and technology. Pointing out that to-day the ability to pursue research increasingly depends on complicated Government organization, Sir Howard noted that one effect of the proliferation of the bodies to which the Government turned for advice on scientific and technical matters had been to diminish the direct relation of the Royal Society to the Government, although many Fellows of the Society served on these advisory bodies. He thought the time was now ripe for reconsidering the specific part which the Society itself could play and that the proposed increase in the technological element in the Society's fellowship could increase its capacity to serve in this way.

Obviously this has a very close bearing on the new arrangements being made for the organization of civil science, and it should not be overlooked that the decision to place the National Physical Laboratory under the Ministry of Technology, announced in the House of Commons on November 26, and to combine the Laboratory

with the National Chemical Laboratory under one director was only taken after discussion with the President of the Royal Society, and arrangements were included to continue the long-standing association between the National Physical Laboratory and the Royal Society. Sir Howard thought that the Society could increase its value to science if it reviewed at this time the methods by which it could furnish information and advice to the Government when required, but he also claimed that in broad outline the proposals of the present Government had taken note of the opinions that the Society had expressed. He fully recognized that the new arrangements, with their numerous sub-committees, required the time and energy of a substantial number of scientists, and for many who were still active in research this involved difficult decisions in determining the allocation of their time and energy—decisions which, as Sir Richard Clarke's Stamp Memorial Lecture on December 1 suggested, are not limited to the scientists or technologists.

It is interesting to note that at the time when the organization of British science is being reviewed, and when special consideration is being given to the channels through which Government is to be advised on problems pertaining to science, an *ad hoc* group of scientists and engineers has been formed by the U.S. National Academy of Sciences to advise Congress. The group will be under the chairmanship of Dr. G. B. Kistiakowsky (professor of chemistry, Harvard University, and chairman of the Academy Committee on Science and Public Policy). An initial survey is being undertaken jointly by the Academy Committee and the House Sub-committee on Science, Research and Development, under the chairmanship of Congressman Emilio Q. Daddario, to determine the areas in which the Academy is best equipped to give advice (see *Nature*, 204, 229; 1964).

Effective organization is an important factor in the wise use of scientific and technical manpower. 60 per cent of Britain's research and development effort is financed by the Government and one-quarter of the qualified manpower is in Government establishments, while 350,000 of the 750,000 people in Britain who have completed full-time courses of higher education are engaged in teaching: we can ill afford to neglect the efficiency of organization and utilization of such a precious resource. Sir Howard was right to remind the Royal Society that the supply of competent advisers and administrators is limited, although its Fellows would welcome the establishment of a body or bodies commanding their confidence and on which they could rely to see that matters of organization were kept under constant review and that big decisions on the deployment of resources for scientific and technological purposes were only taken after the best possible advice had been given to the politicians responsible.

Sir Howard showed that he was well aware of what was involved if the Fellows of the Society accepted the view that it was their duty to do all they possibly could to assist the Government in this somewhat critical stage of Britain's development. He recognized that the establishment of the Ministry for Education and Science had broken the direct link of the Society with the Treasury which had existed for more than a century, but he did not suggest that collaboration would be any the less friendly or

effective. He did suggest, however, that one of the services the Society could render to science just now would be to initiate an examination of how scientific opinion is brought to bear on Government so as to provide a clearer guide through these complexities by which opinions are formed and decisions reached on scientific matters.

The Science and Technology Bill\* now before Parliament and the statements regarding ministerial responsibilities in this field made by the Prime Minister and the Secretary of State for Education and Science in the House of Commons on November 26 are appropriately considered in the light of Sir Howard Florey's remarks. To a certain extent the Government has followed the recommendations of the Trend Report, but no clear principle can be discerned, and while the general arrangement could fairly be described as patchwork, Lord Acton's dictum is worth bearing in mind: "Freedom provokes diversity; diversity preserves freedom". The Road Research Laboratory, for example, is scheduled to go to the Ministry of Transport, while the research functions of the Nature Conservancy are to go to the Natural Environment Research Council under the Ministry of Education and Science, along with the other Research Councils, and not to the new Ministry of Land and Natural Resources.

Whatever reservations may be held as to the structure and placing of the Ministry of Land and Natural Resources, it is, at least at first sight, a Ministry in which it would seem that the internal structure for scientific enquiry and advice should be strong, and this would appear to override any advantage which a research council might gain from its independence of an allied ministry. In any event, the proposed arrangement should provide some evidence on this point, and experience with the Agricultural Research Council under the Ministry of Education and Science instead of the Ministry of Agriculture should also be instructive. How far the arrangements proposed for the Natural Environment Research Council to take over the Geological Survey and Museum, the Hydrology Research Unit, the National Institute of Oceanography and the functions of the Development Commission in relation to marine and freshwater biology and fishery research will meet the views of the Slater Committee or of the Brundrett Committee is not quite clear. So far as both the new Research Councils are concerned, however, the advice of the Trend Committee is largely followed.

It will be noted that the functions taken over from the Department of Scientific and Industrial Research by the Science Research Council in respect of research grants and postgraduate training awards do not extend to awards within the fields of the other Councils. Since the University Grants Committee now falls within the sphere of the Ministry of Education and Science, it remains to be seen in practice how far the principle of diversity of support for research can be maintained: much will depend on the extent to which the reconstituted University Grants Committee preserves its autonomy. The Science Research Council is also to take over the activities of the National Institute for Research in Nuclear Science: under Clause 3 of the Science and Technology Bill, which dissolves the Council for Scientific and Industrial Research and the Department, the activities of that Council are to be distributed among the appropriate Research Councils and other Government departments. The Radio Research Station is to go to the Science Research Council, along

with the Royal Observatories and the scientific space research programme, so also the responsibility of organizing Britain's participation in the European Space Research Organization and the Centre for European Nuclear Research (CERN).

Apart from the Road Research Laboratory and the Tropical Products Research Institute, the remaining stations of the Department of Scientific and Industrial Research go to the Ministry of Technology, which will also be responsible for the National Research Development Corporation and the Atomic Energy Authority. The powers of the Atomic Energy Authority are extended under the Bill to permit the Authority to undertake research and development outside the nuclear field. It is clear, both from the Bill itself and the statements made in Parliament on November 26, that there is a good deal yet to be worked out in respect of responsibilities in such fields as water supply and conservation. This may well appear in regard to building research and some other fields, especially where responsibilities for overseas research are involved.

One conspicuous example of lack of foresight appears to be in the field of information and library services. There is no reference to the position of the National Reference Library for Science and Invention, but the function of the Department of Scientific and Industrial Research in disseminating technical information is to be transferred to the Ministry of Technology, while responsibility for the National Lending Library of Science and Technology, the more general information work, and control of the scientific attachés goes to the Ministry of Education and Science. This is illogical and not easily defensible. The opportunity to develop, under the latter authority, a really comprehensive national library and information service seems to have been missed. Such a plan would seem to be practicable now that the Minister for Education and Science holds so large a share of ultimate responsibility for the provision of the Nation's library services, including those of the universities and technical colleges as well as public libraries. The omission is the more surprising in view of Lord Shackleton's remarks on the need for national organization to deal with scientific information and documentation, at the thirty-eighth annual conference of the Association of Special Libraries and Information Bureau on September 28 (*Nature*, 204, 1025; 1964), and of Lord Mountbatten's announcement at a dinner of the electronics industry on November 10 of a new lending library for research workers in that field in which papers on electronics research will be handled by computer. Lord Shackleton maintained that the Government should accept full responsibility for establishing the necessary national organization for handling information and documentation effectively, and he made a pointed reference to the use of mechanization. Lord Mountbatten made it clear that the imaginative scheme proposed for the electronics industry could be developed to serve all branches of science and industry, and the presence on that occasion of Sir Solly Zuckerman, who also spoke on the information problem, should ensure that these possibilities are kept before the Government, in spite of the division of responsibility between the two Ministries.

How far such misgivings are justified has yet to be seen, and they could well be removed by wise administration. It should be noted, moreover, that the authority given to the Secretary of State for Education and Science and to the Minister of Technology, to incur expenditure in connexion with scientific research, expressly covers research and development in any of the sciences, including

\* *Science and Technology Bill*. Pp. 11 + 12. (London: H.M. Stationery Office, 1964.) 1s. 6d. net.

the social sciences, or in technology. It would seem that the Bill provides sufficient flexibility to enable further changes to be made if necessary, and although the arrangements now proposed do not entirely dispose of objections to the Trend Committee's proposals which were raised at the time (for example, by a Committee of the Geological Society which advocated an Earth Sciences Research Council, and by several Fellows of the Royal Society, who feared the proposals might lead to dangerous fragmentation of marine science and suggested a Marine Sciences or a Marine and Freshwater Sciences Research Council), it should not prove too difficult to meet the objections if the division between the two Ministries is not too rigid. For practicable administration, there must be a limit to the number of independent research councils.

The real dangers lie rather in the pursuit of preconceived ideas; new Ministers, as new as their advisers, have constantly to be on their guard lest either professional tradition or political dogma or administrative convenience lead them astray. That is why it is so essential that critical but constructive thinking about the mechanism of scientific and technological advice should continue in the light of whatever fresh experience can be gathered. This is the only firm basis for an impartial assessment of the arrangements proposed by Mr. Wilson's Government, whatever justification there may or may not be for describing them as 'presidential government' in view of real or apparent similarities to the arrangements in the United States. The justification of any particular structure must rest simply and solely on its appropriateness to the needs and circumstances to be served, when full account has been taken of the implications.

If an end is called for to tendentious or captious criticism, such as has come even from such a body as the Institution of Professional Civil Servants, there can only be welcome for attempts to think out first principles such as have come from Dr. S. Toulmin or more recently from Prof. B. R. Williams and Dr. C. F. Carter in their paper on "Government Scientific Policy and the Growth of the British Economy"\*. These are all concerned, however, with the content of policy rather than the mechanism of advice or the formulation of policy. In the present context the proposal of the Parliamentary and Scientific Committee for a new Select Committee which should examine the annual reports of the Research Councils, of the Atomic Energy Authority, the National Research Development Authority and similar bodies, and also consider such scientific and technical matters as are being considered by Government Departments as a basis for legislation or the formulation of policy, is more relevant. The proposal contemplates that the Committee would call experts as witnesses and that an expanded library and reference service with scientific service with scientific staff would be at its service.

The proposal obviously involves the Government's departure from the steadfast refusal of the Executive in recent decades to provide the House of Commons with adequate services, and its effectiveness will also depend on the recruitment to the House of Commons of an increasing number of Members with scientific and technical background. Apart from the fact that this is essentially long-term policy, something more is required, and in this connexion Mr. R. H. S. Crossman's article, "Scientists in Whitehall", in *Encounter* for July 1964 is pertinent.

Mr. Crossman discusses more especially this question of scientific advice, recognizing that Government must see that professional scientific advice is available in every Ministry wherever it is required and that, as a long-term policy, a steadily increasing proportion of posts at Assistant Secretary and Permanent Secretary level are held by Civil Servants with a scientific background.

So far, as already noted, the present Government has not pursued a consistent policy on the first point, but Mr. Crossman does not suggest that all that is needed is to put more scientists into key positions. Like Sir Henry Tizard, he sees it as ultimately a matter of education and a proper balance between science and arts. Meanwhile the problem is to secure such marriages between the permanent Civil Service and outside expertise as was achieved so successfully during the Second World War, and this means that as a matter of deliberate policy such devices as are immediately open to us must be used. Mr. Crossman suggests, for example, a sharp increase in the size and status of the Scientific Civil Service and a full recognition of the vital role of the outside specialist on temporary assignment to Whitehall. These would provide the type of manpower required for the clear definition of the targets to which the effort of the community should be directed and the systematic use of scientific methods in selecting the aims and in working out the plans to achieve them. Specifically, Mr. Crossman refers to the need to ensure that the chief scientific adviser in each Ministry has direct access to the Minister and that there is sufficient steady movement between Government, university and industry to ensure flexibility of procedure.

Meanwhile, rather more light on the spirit in which the Government proposes to use the new organization, once it has been approved by Parliament, is to be found in the debate on technological development which was opened in the House of Lords by Lord Todd on December 2, particularly in the speeches of Lord Snow and Lord Bowden. Lord Todd in a wide-ranging speech pointed out that financial and social barriers were sometimes more important barriers to technological innovation in industry than scientific or technological obstacles. Moreover, although he admitted that the traditional industries presented the greatest obstacle to development, he questioned whether Britain's past policy towards the research associations had enabled her to get the best value out of what he regarded as a sound idea. He also maintained that we should concentrate our efforts in development on industries with a high content of technological skill and cease to prop up industries that had no real future. With reference to co-operation between industry and the universities, particularly in engineering and at the post-graduate level, he suggested the experiment in some university of a five-year minimum course for an honours degree in engineering, one of the final years being in industry on a sandwich arrangement.

Lord Todd also referred to the need to have enough supporting technicians; he was a little concerned at the prospect of separate Ministries for science and technology as well as a third for aviation, which will also be largely concerned with science and technology. Above all, however, he stressed the need for a unified scientific policy, and it was to this plea that Lord Snow, the Parliamentary Secretary to the Ministry of Technology, responded not simply with a reasoned defence of the division into two Ministries, but by outlining how it was proposed to mitigate admitted drawbacks in the proposed system by common membership of the various councils and

\* "Government Scientific Policy and the Growth of the British Economy" (reprinted from the *Manchester School of Economics and Social Studies*). By C. F. Carter and B. R. Williams. Pp. 20. (Manchester: *Manchester School, Department of Economics, The University*, 1964.)

committees and other formal and informal links for consultation. Besides the use of the development contract and an intelligent adaptation of the purchasing technique used by Mr. Robert McNamara in the United States, Lord Snow said that the Ministry proposed to make extensive use of listening. He stressed the value of Prof. P. M. S. Blackett's appointment on the Advisory Council on Technology, and agreed with Lord Todd's comments on the traditional industries and the research associations, also stressing the need to improve the status of the engineer.

Lord Snow's speech was generally welcomed in the debate, particularly by Viscount Mills, but although both the Earl of Halsbury and Lord Llewelyn-Davis welcomed the establishment of the Ministry of Technology they, as well as Lord Peddie, supported much that Lord Todd had said, as did the Earl of Bessborough. Lord Bowden, who replied on the debate as Minister of State for Education and Science, dealt more specifically with the educational aspect, and more especially with the question of attracting students to courses in subjects such as engineering or mathematics where Britain was experiencing a serious shortage of trained manpower. He welcomed the Earl of Bessborough's reference to the use of development contracts in the American universities, and assured the House that the two Ministries were as close together as it was possible for them to be. He also welcomed Sir Howard Florey's announcement regarding new fellowships of the Royal Society in applied science, and hoped that this would have its effect in the universities and in industry. The feature of both Lord Bowden and Lord Todd's speeches is the extent to which agreement on the organization of Civil Science and on the content of scientific policy cuts right across the bias of party politics. There may be disagreement as to timing or as to the measures to be used to effect particular purposes, but the extent to which agreement is shown to exist should itself encourage the response from scientists and technologists which Sir Howard Florey urged in his anniversary speech to the Royal Society.

## FIRST EDITION OF THE ORIGIN OF SPECIES

### On the Origin of Species

By Charles Darwin. Facsimile of the First Edition with an Introduction by Ernst Mayr. Pp. xxvii+ix+502. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1964.) 48s. net.

THE *Origin* is one of the most important books ever published, and a knowledge of it should be a part of the intellectual equipment of every educated person. Darwin had hoped to produce his book in a leisurely manner. He had completed much of the work and the *Origin* seemed to be shaping into a large volume when, in the third week of June 1858, the postman delivered to him a letter which had been posted some weeks earlier in the Celebes Islands. In this, Alfred Russel Wallace, a travelling naturalist, had forestalled Darwin, for here was a sketch of his theory. The shock to Darwin was great; Lyell and Darwin suggested that an abstract of the theory from Darwin and Wallace should be communicated, and the two papers were read before the Linnean Society of London on July 1, 1858, but were received without great stir.

Darwin then commenced to abstract and condense what he had written, and after another year's work the first edition of the book was published with the sub-title "An Abstract" on November 24, 1859. The publishers

did not expect a great demand for the book and printed 1,250 copies, which sold quickly. A second edition of 3,000 was produced in 1860, a third in the following year, a fourth in 1866, a fifth in 1869 and a sixth and final edition in 1872. Darwin lived for another ten years; but he had so thoroughly sifted and reconsidered his data and inferences that he made no further changes in the book. Many reprints, translations and editions by others have appeared in a period of nearly a century, but almost invariably Darwin's own sixth edition has been used. Prof. E. Mayr, the author of a first-rate book on the *Methods and Principles of Systematic Zoology*, has provided a useful introduction and a new index to a facsimile reprint of the first edition. Thus, the student will be able to follow modifications in Darwin's thought over a period of more than a dozen years. In the earlier edition there is a forthrightness of assertion and, as in other editions, little technical language or professional jargon, so that the work is remarkably accessible to the layman. Darwin's power of marshalling his facts and systematizing the results of thousands of observations is manifest on every page.

There is little wonder that most of the philosophers did not love Darwin, for without recourse to metaphysical ideas he had invaded and conquered much of their territory. As Prof. Mayr points out, Darwin thought in terms of populations rather than of classical Platonic ideas, for, in the latter, the type (eidos) is real and variation an illusion. Thus, Darwin opened the way to the statistical concept which has proved so fruitful in research in biological and other sciences in the twentieth century. Prof. Mayr's introduction leaves us wishing for more. It could be read in conjunction with that of the late Sir Arthur Keith to the sixth edition (Everyman), in which are also printed the additions and corrections to the text in successive issues of the book, some notes on foreign editions and a historical sketch of the progress of opinion on the origin of species, previous to the publication of the first edition of this work.

In spite of Darwin's use of plain words and the tangible rather than the abstract, the book is not easy to read because of its concentration. It was indeed an abstract of a much larger work which was brought to a stop by Wallace's letter. The book will endure in future ages so long as a knowledge of science persists among mankind.

It remains to be said that the edition here reviewed is very worthily produced and contains a little-known picture of Darwin.

W. L. SUMNER

## CHAPTERS OF QUATERNARY HISTORY

### Animals and Plants of the Cenozoic Era

Some Aspects of the Faunal and Floral History of the Last Sixty Million Years. By Dr. Ronald Pearson. Pp. vii+236. (London: Butterworth and Co. (Publishers), Ltd., 1964.) 55s.

DR. PEARSON'S book can perhaps be more accurately described as a series of essays on the history of the mammals and some groups of flowering plants in certain areas of the globe during the past sixty million years. Taken as essays, the chapters give useful summaries of some fields of research that are under active investigation, but there is all too little cross-linking from chapter to chapter.

We are told (p. 26) that a flora with tropical characteristics found at Comstock, Oregon, is of particular interest because it is associated with a marine fauna of known Eocene age. Marine faunas of the western United States are discussed on pp. 102-105, but there is no cross-reference to the plants of the region. The London Clay flora is discussed, but all we are told about its interesting vertebrate fauna is that "the animal remains, with the exception of the Mollusca, are regarded as showing tropical

affinities" (p. 19). There is a very good section (pp. 21-47) describing the Tertiary floras of the western United States from the Eocene to the Pliocene, but beyond two brief separated paragraphs there is no attempt to equate the plants of the landscape with the animals that lived in it. However, there are tables listing fossil mammal localities in the same area and belonging to the same periods. A synoptic table showing both botanical and zoological localities, together with the ecological interpretations that could be drawn from the lists of fossils recorded, would have been of great interest and value.

In the Quaternary section the early Dutch deposits are described, Danish work on the Eemian is discussed, but the German deposits are not referred to at all. The English deposits are well covered, but though the title of the section refers to the British Isles, Jessen's important work on the Hoxnian deposit at Gort in Ireland is not mentioned. Similarly in the Late- and Post-Glacial section the account is heavily centred on England, and reference is scarcely made to the much broader picture of the European woodlands given by Firbas. A considerable amount of North American information is now available, and this too could have been used. Iversen's attempt to trace climatic changes from the varying abundance of pollen of ivy, holly and mistletoe at different stages of the post-glacial period is summarized, but it must be remembered that this work was largely completed before it was fully realized how profoundly man's interference with the woodlands must have affected the growth of these plants.

Radiocarbon datings may have begun about 1940, but uranium/lead datings of igneous rocks were first determined by Boltwood in 1907, and much work on these lines had been done by Holmes and others long before anyone ever thought of the atomic bomb. Emiliani's interpretation of the temperature fluctuations of the surface waters of the oceans which he claimed to have recorded has now been severely criticized by Ericson and others.

The chapters on mammalian palaeontology are very different from those that precede them. Here we have detailed accounts of modern work on the origin and evolution of the different groups, and these will be of great value to vertebrate palaeontologists. In no more than seven pages Dr. Pearson gives a very skilful account of the tangled interrelationships of the numerous proboscidean groups.

As a guide to recent advances in studies of some animals and plants of the Cenozoic Era, Dr. Pearson's book will be of considerable value, but the full account of the natural history of the era must await a great deal of further work.

G. F. MITCHELL

## ISLAND BIRDS

### Birds of the Atlantic Islands

Vol. 1: A History of Birds of the Canary Islands and of the Salvages. By Dr. David Armitage Bannerman. Pp. xv + 358 + 17 photographs. (Edinburgh and London: Oliver and Boyd, 1963.) 84s.

FOR more than forty years Dr. Bannerman has been producing an almost continuous succession of generously proportioned, illustrated works on the bird faunas inhabiting the West African region, Cyprus and the British Isles; with indomitable industry he has now completed 25 volumes. The latest, covering the Canary archipelago and Salvage Islands, is to be followed shortly by two more on Madeira and the Azores.

His first landing on the Canaries was in 1904; and from 1908 until 1913 he made visits there every year, some lasting several months, while he systematically explored the avifauna of the different islands. The First World War put a premature stop to the survey, and, in place of the book he had been meaning to write, he had to be content with a partial presentation of the data, in a systematic

paper in *Ibis*. This ran notwithstanding to seven instalments in 1919-20, and filled almost 300 pages. He was back in the Islands again in 1920, this time writing a descriptive book, *The Canary Islands* (1922). Thereafter he had to turn his attention elsewhere, and the definitive work on the birds has, in the end, had to bide its time for half a century.

The main body of the book is a systematic account of the life-histories of 61 species of breeding birds. This extends and greatly enriches the outline of status and distribution given in the *Ibis* papers, and incorporates material compiled from published work (some of it very valuable) by other authors since 1920. There is naturally a general air of reminiscence, of naturalists active in the early years of the century and of conditions unlikely ever to return to the Islands because of growing population pressure and changes in land-use. So greatly has the vegetation been altered this century that some of the endemic insular bird stocks are now in desperate straits.

The evolution of island faunas is a subject of perennial interest. Endemic species in the Canaries include two sympatric laurel pigeons (both now extremely scarce), the famous blue chaffinch, Meade-Waldo's chat, and Berthelot's pipit. (The canary itself, which of course takes its name from the Islands and not *vice versa*, is an endemic sub-species of the widespread serin.) Bannerman restores the island blue tits to full specific status (*Parus teneriffae*); like many other resident birds, they have distinctive sub-species on different islands.

The Canaries are volcanic, and believed to date from the Pliocene. In spite of being separated by only 60 miles of ocean at their nearest point from the African coast, the affinities of the land-bird fauna are much stronger with western Europe than they are with north-west Africa. This can be presumed to reflect the strong tidal flow of northern migrants through the Islands each autumn and spring. No less than 144 species of non-breeding or off-season visitors are included in a special section on migratory birds, comprising pp. 308-343.

This is a handsome book, with large pages and 13 fine coloured plates of which all but two are the superb work of D. M. Henry. The same artist has also provided many charming and accurate black-and-white portraits of birds which embellish the text; to these the publishers have added several older drawings by Roland Green and Grönvold. Bannerman's style is, as always, lively, personal, unhurried and spacious; in great contrast with most present-day systematic works in which compendiousness usually demands as high a concentration of facts as possible, and no digressions, his book is suited not merely for consultation as a reference work but equally for enjoyable reading—from cover to cover if leisure permits—by any professional or lay ornithologist fortunate enough to turn his attention to these Atlantic isles.

V. C. WYNNE-EDWARDS

## MECHANICAL PROPERTIES OF MATTER

### The Mechanical Properties of Matter

By Prof. A. H. Cottrell. (Wiley Series on the Science and Technology of Materials.) Pp. x + 430. (New York and London: John Wiley and Sons, Inc., 1964.) 70s.

THIS is a remarkable book. In the lucidity with which the material is presented, in the width of matter dealt with and in the originality with which the whole is woven into a coherent unity it breaks completely new ground. Differing as much from the conventional treatment of properties of matter as it does from that of strength of materials, it welds both together on the basis of the atomic structure of the various states of matter. It gives to materials science a reality never before achieved.

What the author has set himself to do is best described in his own preface. "I have tried to give an explanation, in terms of atomic behaviour, of the mechanical properties

of solids, liquids and gases; the traditional approach, by contrast, usually limits such explanations to the kinetic theory of gases and deals with solids and liquids in a severely empirical way. This atomistic approach has led me to discuss the structure of matter, particularly solids, at some length, but I cannot see how to understand the mechanical properties of matter in any other way. Finally, I have also interpreted the subject fairly broadly, so that at several places the text overlaps into neighbouring domains of physics, chemistry, metallurgy and engineering, in order to obtain an integrated view of the whole field as both a pure and an applied science." This is an ambitious programme and could easily become a mass of ill-digested snippets and, to use the author's own words, "a mathematical jungle". That he has escaped both dangers speaks well for his erudition, skill and ingenuity.

Starting with a discussion of the perfect gas, he then deals in succession with condensed states of matter and crystal structure. Three chapters are concerned with elasticity and the propagation of waves and vibrations in solids, and here it should be remarked that they are, to the best of our knowledge and belief, real solids and not the hypothetical homogeneous material of the classical treatment. Fluidity, viscosity and fluid mechanics are considered in Chapters 7 and 12. Surface phenomena are dealt with in Chapter 8, while Chapters 9 and 10 are devoted to plasticity. Finally, in Chapter 11 consideration is given to the problems associated with the fracture of solids. Although the treatment throughout is concerned with the principles involved, a glance at the index will reveal the extent to which these principles are related to actual phenomena. Abrasives and autofrettage, fatigue and brittle fracture, grain growth and the Reynolds number illustrate this, a treatment which will appeal to the reader concerned with the urge to know "what is the use of it all".

Although this work will appeal to very many more, it has been written mainly "for students of physical science and engineering who are at a fairly early stage of their university courses". With this end in view the text has been kept "simple and introductory", the only background knowledge assumed being ordinary "school science and some elementary mechanics and calculus", including some acquaintance with partial differential equations. According to the publisher's jacket, "the treatment is elementary", a claim which would not be accepted by all the students to whom it is directed. In places only the best will be really at home, but even the average student can deal with at least 90 per cent of the material and will benefit enormously thereby. The best will enjoy every word.

Few authors can be so certain that all the work put into a volume has been so well worth while. F. C. THOMPSON

## MOLECULAR ORBITALS

*Molecular Orbitals in Chemistry, Physics, and Biology*  
Edited by Per-Olov Löwdin and Bernard Pullman. Pp. xiii + 578. (New York: Academic Press, Inc.; London: Academic Press Inc. (London), Ltd., 1964.) 157s.

AN anonymous writer in the *University of Chicago Reports* (11, No. 5, 1961) wrote of R. S. Mulliken, "his playing field has been the molecule; the ball has been the electron. In this arena, pure elements recombine into materials and substances which man knows with his five senses. The agent of change is the electron, the negative charge of electricity that locks atoms together or keeps them apart". These words, which reflect Mulliken's attitude to science, are quoted in C. A. Coulson's contribution to this volume written in tribute to Mulliken on his retirement from his chair at the University of Chicago.

Mulliken has been involved in almost every stage of the development of molecular quantum mechanics and molecular electronic spectroscopy. The range of his

interests is easily seen from an examination of the articles in this book. For example, we find papers on molecular self-consistent field theory, group theory, shapes of molecules, molecular spectroscopy, the Huckel theory of  $\pi$  electron molecules, semi-empirical theories of  $\pi$  electron molecules and a final set on the theory of chemical reactions and biological processes. These articles, while not reporting Mulliken's work, discuss those fields in which he has worked.

*Molecular Orbitals in Chemistry, Physics, and Biology*, edited by Per-Olov Löwdin and Bernard Pullman, is indeed a fitting tribute to the pioneer. Its thirty-three papers are the work of some forty-six authors. The authors themselves are drawn from the United States, Europe, Asia and Australia. Some of them have been active for as long as Mulliken. We find papers from Eyring, Pauling and Slater, three of the workers who also pioneered in this field of investigation from the beginning. There is a paper by C. A. Coulson, who since the mid-1930's has been engaged in investigations almost as wide in scope as those of Mulliken. To list the rest of the authors would be rather pointless; let it be sufficient to say that almost all the foremost workers in molecular quantum mechanics have contributed to this volume.

The contents of the book, however, require some comment. Not very much of the work reported here is new, although it is useful to have it collected together in one volume. The opening article by C. A. Coulson, entitled "R. S. Mulliken—His Work and Influence on Quantum Chemistry", is very good indeed. This appreciation of Mulliken's work is itself a pocket-sized review of the work done in this field. J. C. Slater contributes the only other non-technical paper. It is a pity that this contribution is so short, because what there is makes good reading. Slater states that he has just published a volume on molecular structure and that the bibliography has three pages devoted to the work of Mulliken. The quality of the remaining papers is high, but one is left wondering if such detail really ought to be included in such a volume as this. I myself regret that the editors have not published any of Mulliken's work. So many of Mulliken's papers have become standard works that the editors would have rendered a definite service if one or two had been included. Although several of the authors are former students or collaborators of Mulliken there is no contribution from his laboratory. Again, this is a pity.

It may be, as the editors say, that a second volume may be required in a few years time to cover the new contributions from Mulliken. This book, however, is a suitable way to mark the retirement of a great scientist. It is very well produced, and the articles are relatively free from error either of the factual or of the printing variety. Unfortunately the book is very expensive. I cannot see it finding its way into many private libraries. This is unfortunate since it is the sort of book one likes to have. The publishers have done a good job both with printing and binding. Finally, the editors are to be congratulated on assembling such an interesting set of articles by so many front-rank theoretical chemists.

T. E. PEACOCK

## INTRODUCTION TO THE STUDY OF ORE DEPOSITS

### Ore Deposits

By Prof. Charles F. Park, jun., and Prof. Roy A. MacDiarmid. (A Series of Books in Geology.) Pp. x + 475. (San Francisco and London: W. H. Freeman and Company, 1964.) 70s.

IT is a good many years since a text on ore deposits for students (other than translated works) was last published in the English language, although several noteworthy books on this topic have lately appeared in French, German and Russian. Recent advances in know-

ledge have made such a text overdue; and in their chapters (pp. 15-205) on the origin and migration of ore-bearing fluids, on physical and chemical controls of ore deposition, on wall-rock alteration and gangue, on paragenesis and zoning, and on geothermometry, Profs. Park and MacDiarmid convey to the senior undergraduate who will use this work a judicious appreciation of the investigations of the past two decades. The remainder of the book (pp. 207-456), concerned with the classification of ore deposits and the description of well-chosen typical ore-fields, closely follows the system of Lindgren "which represents a fundamental standard by which most United States geologists attempt to classify ore deposits". Perhaps the main demerit of this system, as presented here, is over-insistence on the assumption that hydrothermal fluids "arose directly from an underlying magmatic source", a hypothesis which seems of doubtful validity in connexion with the great stratiform deposits which now furnish a very large part of the metal production of the world. Recognition that igneous intrusions and orogenic activity can stimulate the circulation at depth of intra-stratal brines and other groundwaters, which in turn can derive metals from the rocks which they traverse, seems in many cases to provide a channel between the Scylla of plutonism and the Charybdis of neptunism, on one or other of which hazards, according to the personal predilections of the professional reader, some of the authors' conclusions may be held to founder.

In their introduction, the authors emphasize that "the study of ore deposits and of ore genesis is not an exact science". On the mode of genesis of nearly all the great ore-types of the world—such as gold-uranium bankets, copper shales and red-bed coppers, noritic nickel ores, jaspilite iron deposits, and titanium ore-bodies in anorthosites—there are two antagonistic schools of thought; and in description of these debatable mineralizations an attempt has been made to give both sides of the issues, to a degree which may frustrate the mediocre student who likes cut-and-dried explanations but which will inspire the good student to think for himself. A few factual errors common in foreign text-books have been perpetuated. Thus the statement (p. 388) that the alum shale of Sweden carries as much as 0.5 per cent uranium is analogous to saying that chalk carries as much as 99 per cent silica—this high tenor of uranium occurring in the diagenetic nodules of kolm is altogether different from the alum shale, much as flint is different from chalk. Again, the observation (p. 454) that "platinum is found as well-defined nuggets in the Witwatersrand" is scarcely in keeping with the facts that the principal platinoid present is osmiridium, that it rarely if ever exceeds 0.1 mm in grain size, and that the tenor in the Witwatersrand ores (only four times the Clarke) is comparable to that in many gold-uranium veins of undoubted hydrothermal parentage. But these criticisms are very minor ones. In a text for undergraduates one would have welcomed a little about non-metallic ores—minerals such as diamond, magnesite, asbestos, and most other non-metallics are not dealt with. Despite this, however, the book fills a present need. It will be warmly welcomed and will deservedly have a wide circulation. C. F. DAVIDSON

## CORRELATION BY FOSSILS

### Time in Stratigraphy

By Dr. Alan B. Shaw. (International Series in the Earth Sciences.) Pp. xiv + 365. (New York: McGraw-Hill Book Company, Inc.; Maidenhead: McGraw-Hill Publishing Company, Ltd., 1964.) 10.50 dollars; 81s. 6d.

THE valuable part of *Time in Stratigraphy* consists of the exposition and illustration of a new method for improving stratigraphic correlation by fossils. By applying his method to certain strata in Texas, Dr. A. B. Shaw demonstrates that it is possible to subdivide the succession

much more finely than by the present method of zoning. As a consequence, different sections may be much more accurately correlated with one another than has hitherto been possible. Should trial establish the validity of the method, its application to a variety of successions could lead to a breakthrough in various evolutionary and sedimentation investigations.

The method involves the determination of a standard succession of ranges of fossils, measured in units of length through a particular suitably chosen reference-section. The ranges are those not only of fossils occurring in that section, and extended where evidence from other sections shows an earlier entry or a later disappearance, but including also points of entry and disappearance of other species interpolated from other sections. The procedure used in interpolation from other sections into the standard is the essence of the method. In comparing another section with the standard, two processes are involved: (a) the differing thicknesses of strata corresponding to equal intervals of time and arising out of the different rates of accumulation of the two sections must be allowed for; (b) the two successions must be correlated. Both processes are carried out at the same time by a statistical method which can take account of all the different range limits common to both sections. In practice, not all range limits are used in the calculation, as some can be shown to be more valuable than others in particular cases.

By the successive incorporation into the standard of data from a series of sections, the quality of the standard is continuously improved. When all available suitable sections have been used, it is possible to go back over the sections and compare them successively with the improved standard which is thereby continuously further improved. The revision can be carried on along these lines until no further improvement results.

The statistical procedure used in interpolating data from other sections into the standard can now be applied for the comparison of any other section with the perfected standard. Thus the best possible correlation can be obtained.

It can be seen that this method of correlation is superior to present methods, in that it makes use of far more data and because it is much less arbitrary and subjective. The statistical technique is simple and the calculations can be made readily on an ordinary desk calculating machine.

On theoretical grounds, the method may be criticized for its assumption that rates of sedimentation are reasonably uniform throughout a given section. It would not be difficult to investigate this assumption by dividing up various sections and testing the variation in rate of accumulation in each part. Indeed, this ought always to be done before correlations are attempted if there are marked changes of lithology or other grounds for suspecting lack of uniformity during deposition.

The price of the book is obviously a consequence of the large number of complicated tables. These are absolutely necessary in the main, though there is some avoidable repetition and the columns of standard equivalent levels in Tables A-4 and A-6 are unexplained and confusing. It would seem that an attempt has been made to make the price more palatable by throwing in something extra, namely the first seventy-one pages of the book, which are concerned with general principles of stratigraphy. On the basis of this first part of the book, it has been given the rather meaningless title *Time in Stratigraphy* which suggests that the book is a contribution to general stratigraphy. Unfortunately there is insufficient reference to actual examples to make the discussion of principles worth while, especially where these principles are either new or formulated in a new way. In any event, all this is unnecessary, as the later part of the book does not depend on any new principles or new application of old principles. The book is only of real value for its new method of correlation, and it is not to be recommended to general students of stratigraphy. S. SIMPSON

## Organic Chemistry

By Dr. I. L. Finar. Vol. 2: Stereochemistry and the Chemistry of Natural Products. Third edition. Pp. xii+690. (London: Longmans, Green and Co., Ltd., 1964.) 50s.

THE third edition of Dr. Finar's book brings an already popular and successful text up to date, with references to the 1963 literature. The overall scope is unaltered, approximately one-third being devoted to stereochemistry and the remainder to natural products. In the main the revision consists of insertions into the old text, but Chapter 3 ("Nucleophilic Substitution") has been reconstructed and now includes a concise account of neighbouring group participation. Chapter 8 introduces the concept of bridged (that is, non-classical) carbonium ions, which is utilized in later discussions.

Dr. Finar's book presents a lucid, well-illustrated account of stereochemistry and a panoramic survey of the chemistry of natural products. Indeed, the reader has at hand, in one volume, such topics as carbohydrates, steroids, purines, porphyrins, alkaloids, flavonoids and terpenes. Such a menu cannot fail to attract customers, and at this price it is a bargain. As may be expected, such a compilation of material is only made possible by condensation, and there is a tendency to present facts without explanations or life-giving commentary. Thus the subtleties of the patulin molecule are glossed over, the stereochemical implications of the biotin synthesis are lost, the chemistry of flavonoids is treated too factually and the teaching potential of terpene chemistry is only hinted at. On the other hand, a real attempt is made to comment on the underlying principles of the Woodward sterol synthesis, and elsewhere the author makes commendable use of cross-references where space considerations forbid a full discussion.

Some readers will feel disappointed that, in spite of the references on the cover, and in the index, to infra-red, ultra-violet and nuclear magnetic resonance spectroscopy, the application of these techniques is not really demonstrated in the text. I could find only one case (p. 383) in which spectroscopic data were given. Other entries consist of a phrase such as, "Infra-red studies showed the presence of two double bonds".

With these reservations this is a valuable book which provides a useful basis for further reading. It has a very comprehensive index, formulae and diagrams are well reproduced, and the cross-indexing is excellent. The use of a larger page size in this edition is also welcome.

G. L. BUCHANAN

### Etude Critique des Bases de l'Interprétation Actuelle de la Mécanique Ondulatoire

Par Louis de Broglie. (Traité de Physique Théorique et de Physique Mathématique, Nr. 21.) Pp. ix+93. (Paris: Gauthier-Villars et Cie., 1963.) 28 Francs.

THE metaphysical interpretation of quantum mechanics will probably continue to worry philosophically-minded scientists and scientifically-minded philosophers for many years to come. The essential question seems to be: Do things really happen when physicists are not making measurements, or is the detailed history of the world merely a vast collection of possibilities and probabilities? One feels that it should be possible to answer this question in a way which satisfies common sense, but the combined efforts of physicists and philosophers of science have so far failed to do so. It is therefore a philosophical event when the father of wave mechanics gives us his mature reflexions on the paradoxes of quantum theory.

Louis de Broglie's book is short and meaty. It is written with a clarity of style which is all too rare even in the works of literary men, and he lays before the reader simply and cogently the paradoxes of the orthodox

theory of measurement. He states fairly and exactly what has become known as the Copenhagen interpretation of quantum theory, but shows that it leads to assertions which are very difficult to reconcile with the doctrine of physical realism. He does not question the correctness of wave mechanics but merely its completeness, and the reader begins to wonder whether de Broglie may be about to present a satisfying escape from the famous paradoxes.

But that would have been too much to hope for. What de Broglie offers us is, in fact, his old theory of the 'double solution' in which the particles of wave mechanics are somehow guided by the waves representing them. de Broglie recognizes that he has not demonstrated the existence of the 'double solution', or its consistency with the general postulates of quantum theory. In this he is admirably honest, and even if one doubts the value of this attempt, one must admire and respect the complete intellectual integrity with which it is put forward and criticized.

*Etude Critique des Bases de l'Interprétation Actuelle de la Mécanique Ondulatoire* is an object lesson in clear, imaginative and honest thinking about physical reality, and is to be heartily recommended to anyone who is seriously interested in the relation between physics and metaphysics.

H. C. LONGUET-HIGGINS

### Insect Pathology

An Advanced Treatise. Edited by Edward A. Steinhaus. Vol. 1: pp. xvii+661; 22 dollars, 157s. 6d.; Vol. 2: pp. xiv+689; 23 dollars, 164s. 6d. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.)

VOLUMES 1 and 2 of *Insect Pathology* comprise a collection of papers written by 35 international authorities, edited by Edward A. Steinhaus.

Volume 1 deals with physical injuries; chemical injuries; nutritional diseases; genetic diseases and aberrations; tumours; the micro-organisms of healthy insects; the pathogens of vertebrates and plants as pathogens of their acarine and insect vectors; immunity in insects; physiopathology and histochemistry; predispositions and interrelations in insect diseases; the nature of infections caused by nuclear-polyhedrosis viruses; the nature of nuclear-polyhedrosis viruses; the cytoplasmic virus diseases; the induction of virus infections; granuloses of insects, and rickettsiae and rickettsioses.

Volume 2 contains chapters on the taxonomy of entomogenous bacteria; diseases caused by certain spore-forming bacteria; the milky diseases; non-sporulating bacterial pathogens; *Coelomomyces* infections; entomophthorales infections; diseases caused by hyphomycetous fungi; *Gordyceps* infections; sporozoan infections; infections caused by protozoa other than sporozoa; nematode infections; pathologies caused by insect parasites; the epizootiology of infectious diseases; microbial control; the commercial production of insect pathogens; the background for the diagnosis of insect diseases, and techniques in insect pathology.

This list of chapters indicates the comprehensive scope of the volumes. The subject is of obvious interest to those in the life sciences concerned with entomology, either directly as entomologists or indirectly as virologists, botanists, parasitologists, chemists, pathologists. It is now realized that the control of insect-borne infections in man, animals, plants and crops must not be undertaken with unthinking enthusiasm, but must be directed to conservation and the appropriate exploitation of Nature by using sophisticated measures. For these measures, a detailed knowledge of insect pathology is essential. *Insect Pathology* is both instructive and educative, and it is therefore essential reading for those involved in advising on control measures against insects or the organisms they transmit.

W. E. KERSHAW

## THE WORLD, THE FLESH AND THE METAL\*

## THE PREROGATIVES OF SYSTEMS

By STAFFORD BEER

Managing Director, SIGMA (Science in General Management, Ltd.),  
Croydon, Surrey

## The Seminal Idea

COMMANDING concepts arise in science which seem to roll up the universe into a ball, declaring: it works thus. I am thinking of such notions as inertia and entropy. The names of these concepts do not denote any discoverable thing out there in the world at all. They denote sophisticated ideas that scientists have about the way the world is arranged, or perhaps read into the world. What is out there is a manifestation of the idea; and that manifestation is pervasive, once the idea is sufficiently clear to be called obsessive.

The old way of talking about these concepts was to legislate about them, and to set up Laws of Nature. Who passes these laws is not clear, but certainly God alone may repeal them. So clustering about the concept of inertia are the laws of motion—together with a considerable body of amendments which encompass relativity; and clustering about the concept of entropy are the laws of thermodynamics—together with special versions of the enactments for other territories, such as statistical mechanics and information theory. These laws seem to be very unusual ones indeed; for there is no way of repealing them—once the Deity is defined in their own terms as a store of negentropy.

Now concepts of this kind are very difficult to understand, because there is no ostensive definition. Hunting down inertia is like hunting down the snark; the only one who actually saw it “softly and suddenly vanished away”. The result is it takes a long time before the concepts which are most potent in the scientist’s interpretation of the universe are manipulated with ease in our thinking. As evidence of this contention, consider the adjectival form of the terms already mentioned. Physics acquired the concept of inertia in 1687, through the *Principia*. But it was a hundred and sixty-two years before anyone invented the adjective, and spoke of ‘a weight of inertial resistance’. Where would science be without that word to-day, a mere hundred years later? As to the word entropy, the centenary of the birth of which falls in 1965, we are still so unsure of ourselves that there is no official record that the adjective has been coined yet. I have in fact coined it myself, and offered such phrases as ‘entropic drift’; but no one seems to want them.

The point of all this is to suggest that the concept of system is another such seminal notion, which we are only now beginning to understand. This word has also been used since the seventeenth century; and is certainly well understood in the rather special sense of an assemblage which is usually small, usually connected together deterministically, and usually well defined. But we cannot roll up the universe into that sort of ball, nor declare it works thus. Patently the universe is not, nor is it compounded of, that sort of system. Yet a system in another sense it clearly is, and any part of the universe is clearly a system in that same sense. Secondly, the syntactical clue to our unease in the manipulation of this wider concept is again present. For the adjective which means ‘pertaining to a

system’ is not ‘systematic’ (which means something quite different) but systemic; and that is a word one seldom hears. It took a hundred and eighty-four years to achieve the adjectival form this time, even in a limited physiological context. As an adjective of general relevance, the word systemic has been with us for only a hundred years, and its use is now marked ‘rare’ in the dictionary.

In short, we do not think about the systemic nature of things, we prefer to consider them in isolation. Stepping smartly down from these philological clouds, I point to a number of practical examples. The brain, a company’s profitability, a computer and the National Health Service are all integral systems. But we talk gaily about the motor cortex as if the rest of the brain were irrelevant to movement. We talk about the cost of making a product as if it did not matter what opportunities to make other products were foregone in making this one. We talk about the reliability of an electronic component as if this meant something independently of the failure rates of associated components in an operational ensemble. We talk about the cost of prescriptions under National Health as if this were independent of the doctors’ attitude to whether the patient bears a charge or not.

The seminal notion of system-as-pervasive in science is really very new, and we are not trained to think in systemic terms because our scientific approach has been analytical to the ultimate degree. We took things apart, historically, and described the atomic bits. We did our experiments, historically, on these bits—deliberately holding invariant the behaviour of other bits with which in fact they were systemically interacting in real life. Now advances in statistical method have enabled us to be more ingenious than this to-day; we can afford to let a number of things change at the same time, and sort out the meaning of the experiment by multivariate analysis. But this is a mastery of technique, not a change in methodology. The result is that our only approach to system is through aggregating bits. No wonder that we do not advance in understanding really big systems, then, and that the very connotation of this word system includes such question-begging epithets as small, determined and well defined.

The concept of system in its widest meaning is a cybernetic concept. Big systems are the topic of cybernetics. The systemic character of the world is the clue to its control; just as the inertial character of the world is the clue to its movements, and the entropic character of the world is the clue to its energies. Thus the contention is that the ‘laws of control’ are the prerogatives of system—wherever and whenever it is defined. And this is why I have taken liberties with the catechism in the title. For the prerogatives of system are pervasive, whether we speak of the world at large, or the flesh of our own bodies, or the metal of the ironmongery we invent as engineers.

## Methodology of Models

If this concept of system is so new and so important, how shall we attack it, how comprehend and manipulate it? In a paper written five years ago<sup>1</sup> I gave a philosophical approach to this problem. To-day the approach will be essentially mathematical.

\* Substance of the 1964 Stephenson Lecture delivered before the Stephenson Engineering Society, University of Newcastle upon Tyne, on November 26.

When an engineer looks at a big system (as already defined here) and recognizes its systemic character, he may well perceive its structure in terms of servomechanics. He draws rings around various activities, or sub-sets of events, in his mind, and observes that they are linked together by messages. That is to say, that the input to one sub-set is the output of one or more other sub-sets. For example, production is an activity which responds to a demand expressed by a market, while selling is an activity responding to a production output. The engineer may then recognize that what happens in each box of the system may be regarded as a transfer function applied to the signals that connect it to other boxes. If the macrosystem he is thinking about can once be defined as closed, as in the case of the marketing-production-marketing example, he is in business as a model-builder. The process soon becomes exciting. In order to attain to an ever-more-accurate account of what the big system is doing, the model-builder may insert all sorts of boxes in his design, until the model is very complicated indeed. Very soon he will see the need for local regulatory devices in the microsystems which comprise the macrosystem. This will lead to the insertion of closed-loop feed-back circuits, in which outputs are monitored by comparators, and inputs modified by some function of the error signal thereby formed. It is often possible to obtain a strikingly good analogue, expressed in servomechanical terms, of a fairly big system of world events in this fashion.

In fact, this is one example of the way operational research works. The scientific model conceived by an operational research team will depend on the kind of system being studied and on the versatility of the team itself. We are all conditioned by our training and experience. It can scarcely have been fortuitous that Prof. M. J. Lighthill chose to represent the flow of traffic with a model from fluid dynamics, or that Prof. A. Tustin sought to model the economy by just the kind of servo-system that I have been describing. This is not because the big systems of real life are 'really' hydraulic or electrical in character, but because Lighthill and Tustin are the distinguished men they are, and because the systemic character of the world is pervasive. This is why an operational research group is supposed to be interdisciplinary. It is my job to hold back a colleague who is determined to model a management structure by an anthropological model taken from the tribes of the Western Pacific, if this turns out to be rather unhelpful. Equally I expect my colleagues to intervene if my own habit of modelling company organizations on neurophysiological systems runs away with me. They always do intervene, as it happens; but I still think that the brain, supported as it is by many million years of research and development, must offer good advice on how to make a control system viable. Which just shows how preconditioned I am. Anyone who wishes to examine more closely how operational research makes use of models from science may refer to another paper<sup>2</sup>, in which various examples are given—including the electrical circuit of a servo-model of an actual production system.

But, assuming that this talk of models is now understood in a general sense, I propose to examine rather more rigorously what is going on when a model of one activity is taken from another activity. Here it should be borne in mind that our comprehension of anything at all is likely to be expressed to ourselves in terms of something else which we know that we understand; which is another way of saying that everything is a model of something else. If you should ask: what constitutes the prior structure of which other things are models?—then maybe the answer belongs to psychoanalysis, and must be expressed in terms of elemental and traumatic experiences.

Consider a big system out there in the world. It may be a firm interacting with its environment of markets in a search for survival; it may be a company competing

with another company for a larger share of a zero-sum pay-off; it may be a capitalist economy in which a socialist chancellor sits like a Maxwell demon increasing the entropy of wealth. (Please note in passing how, simply in order to nominate three samples of big systems, I have already invoked three models: from ecology, from game theory, and from thermodynamics.) In trying to understand these things as systems, we must detect in them whatever is systemic. This sounds tautologous, but it is not really. For we do not have full knowledge of what these systems are like—they are immensely complicated; and we do not have full knowledge of what constitutes system anyway—science is not yet omniscient, and we ourselves are relatively ignorant.

Now I shall discuss this problem in the language of group theory, for reasons which will be made specific later on. The point is that we need as rigorous a statement of this complicated methodology of models as we can get. It is in fact high time that some such attempt were made, for the very word 'model' has fallen into an unhelpfully casual usage. Some people use the word as synonymous with 'mathematical equation'; others treat the word as if it meant 'hypothesis'. A model is neither of these things. It is something that opens up a virtually new way of doing science.

Thus if we call the set  $M$  of elements  $a$  the totality of world events which we propose to examine, then the systemic configuration of events which we know about is a sub-set  $A$  of set  $M$ . If we call the set  $N$  of elements  $b$  the totality of systemic science, then the configuration of system which we ourselves understand is a sub-set  $B$  of set  $N$ . The process of creating a systemic model may then be described as a mapping  $f$  of  $A$  into  $B$ . By this I mean that for every element  $a \in A \subset M$  there exists a corresponding element  $b \in B \subset N$ , and thus  $b = f(a)$ . The image of the sub-set  $A$ , namely,  $f(A) \subset N$ , is the model. If we are able to exhaust the elements of  $A$  and to nominate their images in  $B$ , we have every hope of creating an isomorphic model. This means that there exists a complete inverse image of  $B$  under mapping  $f$  in  $M$ , so that  $f(A) \subset N = f^{-1}(B) \subset M$ . This is the state of affairs, expressed group-theoretically, which the operational research man is trying to reach.

Now an isomorphism is important because it preserves the structure of the original group in the mapping. Typically, if it is possible to perform additions inside set  $M$ , those additions will remain valid when the same operations are performed on the images of their elements in set  $N$ . It is this persistence of relationship when the mapping is done which makes a model operate as a model. So, if  $a_1$  and  $a_2$  when added together equal  $a_n$  in set  $M$ , it can be shown that  $f(a_1)$  plus  $f(a_2)$  must equal  $f(a_n)$  in set  $N$ . Now comes the interesting comment. The conditions can be set up in which the same answer  $f(a_n)$  in set  $N$  is obtained from the mapping  $f$  whether the transformation is effected before or after the mapping occurs. That is to say, we may either add the original elements in  $M$  and transform the answer under  $f$ , or we may transform the original elements first and then add them. The result will be the same. Formally:  $f(a_1 + a_2) = f(a_1) + f(a_2)$ . When one group is mapped into another group and this condition is generally fulfilled, the mapping is called homomorphic.

These elementary definitions are included so that the argument can be made quite clear. Because it is possible to coalesce elements of  $M$  before transforming them, without losing the capability of a mapping to preserve structural relationships as discussed, it is clear that a homomorphism may have fewer elements than its inverse image. In the case of the model, then, the mapping of  $A$  into  $B$  turns out to be a mapping *onto* a sub-group of  $B$ . Isomorphism turns out to be a special case of homomorphism, in that  $f(A) \subset B$  turns out to mean  $f(A) = B$ : the one-one correspondence of elements with which we begin is maintained. But for any other sub-group of  $B$

other than  $B$  itself, homomorphism involves a many-one correspondence, and the inverse mapping  $f^{-1}(B)$  will not exhaust the elements of  $A$ .

It is suggested, then, that the models of big systems that we entertain are homomorphisms of those systemic characteristics of the big system that we can identify. The homomorphic group  $f(A) \subset B \subset N$  is the particular model we use. It is in practice extremely difficult to include in this model all the features recognized in  $A$ , and typically we do make the many-one reductions mentioned. Thus, for example, we undertake production costings as if the behaviour of all three shifts in a works were indistinguishable, and as if two similar products were identical, and as if materials were consistently uniform—although we actually know that none of these simplifications is true. Then the effectiveness of the model as predictive depends on the choice of an effective transformation by which to map. If we add up the outputs of three shifts and then transform the answer by some mapping into the model, it is no use supposing that any calculation, comparison or prediction undertaken in the model can be worked backwards through an inverse mapping which will distinguish between the shifts. On the other hand, it is necessary to handle only a third of the elements we know about inside the model. A definite choice has been made to jettison modelling-power in favour of economy in the recording and handling of data. This is acceptable, so long as the choice is deliberate rather than accidental, and so long as it is remembered as a limitation in the model.

Secondly, however, there is a further loss of modelling power in the facts that  $A$  is a sub-set of  $M$  and  $B$  is a sub-set of  $N$ . Now an interdisciplinary team of scientists can minimize the losses of modelling power due to  $B \subset N$ . Because such a team can examine all the major sub-sets of  $N$  before deciding to use one specific group  $B$ ; it may even experiment with other groups too. But the losses due to  $A \subset M$  are more serious, and may be disastrous to the exercise. For if what we recognize in a big system is not what is really important about its systemic character, the ability to predict  $A$  may not help much in  $M$ . In other words,  $A$  is itself a homomorphic mapping of  $M$ , and one which by definition we cannot properly specify. Remember that  $M-A$  was acknowledged to be systemically unrecognized from the start. We may know that our knowledge of a big system does not exhaust it, without having the faintest idea of the character of the knowledge that is missing.

It is hoped that this attempt somewhat rigorously to formulate what goes on in model-building will prove helpful in pin-pointing what we can and cannot do. The ordinary operational research exercise works, and we can see why. It is possible to advance what we understand about a stock-holding system, for example, to the point where  $A$  approaches  $M$  asymptotically. It is possible to examine most  $B$  of  $N$ , which is to say most scientific approaches to the scientific totality of understanding about such systems. If we know what the stockholding system has to do, if (as the operational research man would say) we can define its criteria of success or objective function, then we can define a homomorphic mapping  $f$  of  $A \simeq M$  onto  $B \subset N$  which preserves the stochastic relationships in which we are interested. More especially, we can do this in such a way that the inverse image of  $B$  under mapping  $f$  yields a set  $f^{-1}(B)$  of elements in the real system  $M$  which are useful.

The difficulties about doing successful operational research in various circumstances can now be made quite specific. First, the modelling will not on the average work well if  $N-B$  is large: this happens if the operational research team is not corporately versatile. Secondly, the modelling will not work at all unless  $f$  is well defined: this entails good empirical research into what the system really has to do. Thirdly, the predictions of the model will be of no actual use if a modelled outcome  $\varphi(b_1, \dots, b_n)$

turns out to have a pragmatically indiscriminating inverse  $f^{-1}(\varphi)$  in  $A$ . This also entails good empirical research into the forms of many-one reduction. Fourthly, the modelled predictions though useful will not exert what could be called control unless the  $M \rightarrow A$  homomorphism captures the systemic character of the big system *in extenso*. This again appears to be a matter for good empirical research, although there is more to say.

Contrary to increasingly current belief, then, operational research is empirical science above all. The mathematical models dreamed up in back rooms are useless unless they can meet the four kinds of difficulty enumerated, and this cannot be done remotely from the world. But that is by the way.

### Basis of Systemic Control

If the ordinary operational research study works for the reasons just given, it is easy to see why we encounter difficulty in extending its scope to the really big system. It is not the difficulty of procuring the homomorphic mapping  $A \rightarrow B$ , which practice and scientific skill can encompass. It is the difficulty of procuring the homomorphic mapping  $M \rightarrow A$ . Now if we rightly called the mapping  $f(A) \subset B \subset N$  the model, it is the complete inverse image of this model in  $M$  that constitutes a sentient control. The point is one of some subtlety, and repays a little thought. It says that deliberative control can be exerted only through the systemic connectivity of the big system that we recognize; and, moreover, that we are enabled to exert that control only via our model of how it works, with an efficiency that depends on the relevance of the mappings  $f$  and  $f^{-1}$ .

Interestingly, this deliberative control is not primarily what does control any big system. It is not adequate to the task. No one imagines that the set of actions open to being taken by a Chancellor of the Exchequer constitutes the control of the economy; it constitutes at best an error-controlled feed-back loop of either positive or negative sign. And the managing director who believes that he constitutes the control of the firm is deluded for the same reason. The reason why this must be so is given by the volume of information defining the behaviour of a big system. In cybernetics, we call the number of distinguishable states that a system may take up its variety. Clearly, the big system proliferates variety; and clearly this variety is not readily handled by a control system which cannot absorb it—which is choked by it, or confused by it, or otherwise overwhelmed. I have already said that ideally  $A$  should tend to equivalence with  $M$  under some homomorphic transformation. This was meant to ensure that the systemic structure of the big system would be preserved in the understood version of its nature which was to be modelled. What we now go on to say is that the measure of variety evinced by the big system must in some sense be paralleled in whatever is actually controlling it.

Examine this proposition in terms of the thesis already developed. We want a model of the big system  $M$  competent to determine its actual rather than deliberative control mechanisms. Since we do not, by definition, know what these are, we need to preserve a one-one correspondence of elements. What then is isomorphic to a big system? It is inconceivable that we should go away and construct another system of equivalent variety—for this really is a big system, and our model would have to be as large. The group-theoretic formulation gives the clue to the answer. Cayley's theorem declares that every finite group is isomorphic to a certain group of permutations of itself; and it is part of the proof to show that one of these is the identical permutation. In other words, the isomorphism we seek for the big system is itself. Hence the big system  $M$ , to which is clamped another system  $A$  which is in fact itself, is to be called controlled.

Do not imagine that this conclusion is vacuous. It is, after all, the realization that an isosceles triangle  $ABC$  is congruent with the identical triangle  $CBA$  that enables us to prove, without construction, that the base angles are equal. If we try to give material substance to the mathematical abstraction of the big system's isomorphism with itself, we shall, so to speak, have to think of cleaving the system in half through its plane. Then every element is twinned, and the idea of what constitutes effective control suddenly becomes blindingly clear. Every player is marked by another player; or, to use another metaphor, half the population are policemen keeping one-to-one guard on the other half.

The law of control which has emerged is, I believe, a new formulation of Ashby's law of requisite variety<sup>3</sup>. It says, in effect, that control can be exercised only by a controller having at least as high variety as the system to be controlled. This is what happens in big systems, because it must. Two halves of the system are monitoring each other; though woe betide any glib observer who imagines he can determine the boundary between them. It is not as easy as that. The two sub-sets are interpenetrated; and, one suspects, elements move in and out of both sub-sets continually. Requisite variety in a controller is the power to absorb the variety proliferated by what is to be controlled, but this power is disseminated throughout the system rather than being concentrated in a control box.

However, there is better news—if we are cautious. Electrons are continually being exchanged between any object and its surroundings, but this does not in practice deter us from identifying objects and declaring that they persist. If we had sub-atomic magnitude ourselves, it would matter very much: doubtless we should not be able to identify these objects at all. If, then, we look at our big system as compounded of sub-systems which exhaust the whole, we may well make arbitrary rulings about what constitutes one part and what another, but we shall have preserved requisite variety. For although there is no means of saying exactly what is included in any sub-system, and although we may be quite unable to analyse the relationships which subsist between the elements of these sub-systems, we shall still be able to talk about control. Control is precisely the stable state of the variety interactions between the sub-systems nominated.

How does this account differ from the original one in which the engineer looked for the servo-system within the big system? In the first place, it is exhaustive—by logical definition. But, more important, it does not see communication as a signal passing from one transfer function to the next in a thin white line. It sees communication as interpenetrative between the sub-systems which are richly interconnected—(in the limit) element by element. Yet, more important still, it sees systemic stability itself as the object of the system, and not the holding steady of an arbitrarily assigned output—which is the usual criterion of control engineering.

These outcomes of the discussion give most of the leads which are required to answer the initial question: how do we attack, comprehend and manipulate the systemic character of the universe? They involve, I fear, a revolution in thinking for the trained scientist. No longer do we aggregate bits of the system, which have been adequately investigated, into even larger well-understood systems, which eventually (but when, indeed?) ought to approximate in size and scope to the big system under investigation. Instead, we begin by carving up the not-understood big system into interacting sub-systems, and we ask behavioural questions about the resulting homeostats—which are the stably interacting parts. This can be done, and can result in useful statements about the big system itself. Comprehension begins with observations about the way in which two halves, or better still  $n$  ths, of the big system interact, although there is virtually no knowledge

about the contents or internal structure of those halves or  $n$  ths. Comprehension is extended by resolving (in the optical sense) these structures to an ever-increasing degree. But we should not imagine that we shall ever reach the atomic parts and their relationships—which are the very entities with the close examination of which orthodox science is accustomed to begin.

Anyone who finds this too puzzling should forget that he is a scientist for the moment and remember that he is a man. How is it that we can make useful predictions about the way each other's brains work? We do a reasonable job; for people do not constantly surprise us, rather the dispiriting reverse. Perhaps we do it by drawing inferences from other people's behaviour, their responses to our stimuli, over a period; perhaps we argue by analogy with our own responses; perhaps we do both. In any event we do it by making models, by mapping behavioural structures on to each other; by juxtaposing; by interacting. What we quite clearly do not do is get down to that mess of pottage, a brain newly excavated from its cranium, with a microscope. If we did, and escaped hanging, we should still not learn enough to make predictions about people's behaviour. The classical method of enquiry would encumber us with the investigation of the basic nerve cell, the atomic component, called the neurone—from which we would work outwards to the big system, the cerebrum. According to the American cybernetician McCulloch (who very possibly knows) the transfer function of a neurone is to be defined only in terms of an eighth-order non-linear differential equation. There is no guarantee that any two neurones have an identical transfer function, and the brain contains ten thousand million of them. Next, we should need to know how they arranged and interconnected. The fact that all our lives we lose about a hundred thousand a day (they just pack up) is another complication. No: it just will not do.

Return then to the notion that requisite variety is supplied in natural systems, and that deliberative control is based on a model of a sub-set of the actual control mechanisms. What the would-be controller, or manager, has to do is to intervene in these natural processes rather than to impose some control arrangement on them. Good managers intuit that this is their task. The trouble is that so many of the 'experts' who seek to advise them do not always understand this point, unless the big system is a person. In that special case, human prerogatives are invoked to say that people ought not to be controlled by the imposition of restraints on their freedom: I speak of an ethical imperative. Certainly, some restraints are imposed, in the interests of the community at large; but if we want a particular man to do a particular act we do not contemplate using a pistol, or drugs or hypnosis. We have to organize the system of which the man is a part in such a way that he does what we want of his own accord. This is the right way to control any big system, such as a firm or an economy; not because of ethical imperatives but because of cybernetic laws. For the implicit control of the big system, which requisite variety guarantees, is carrying the system to a more stable condition naturally.

The management task is to arrange its pay-off objectives in relation to the system's own built-in objective of stability. The best way to express this rule is to say that the system has an informational entropy which carries it towards a more probable state. Management needs to arrange the system so that the most probable state is the desired state. This means that the natural force of entropy is harnessed as a control force in the system. It also means that the system offers us an amplifier of our control signals free of charge, and a complete set of appropriate control circuits for distributing control signals to the right places in the system—even though we have no knowledge as to where the right places are.

If this sounds too good to be true, remember that the job can be done effectively only if we use a model which is

an appropriate homomorphism. The 'experts' of whom I complained just now are people who imagine that their heads contain this model, and that their own *savoir-faire* is a sufficiently good account of the inverse mapping. Why do economists disagree as to the correct governmental action in a given economic crisis? Surely it is because they pass off hypotheses about the way the country works as models with known mappings; so that any two of these non-models will read different deliberative control policies into the inverse image, which are quite likely to be inconsistent if not contradictory. The same is true of advisers to firms, transportation experts and so forth. The control of big systems demands a prior investigation of the natural control homomorph, and a scientific account of what entropies are involved. From this we can learn how to use the entropic drift as a control device. It is the only way to generate requisite variety in deliberative control for the inverse mapping  $A \rightarrow M$ .

### Systemic Control in 'The World'

When we come to consider applications of these arguments to the world in general it is natural to turn to national affairs. For here are the big systems with which it is most important that we learn how to deal. There are, of course, international affairs, if we wish to set the sights higher.

Now it is possible to argue that most of the troubles we encounter in deciding on policies at the national and international level derive from our habit of dividing the system, which is too big and too complicated to handle integrally by classical methods, and trying to compute with the pieces—or sub-systems. The reason why a world which is affluent in some places and penurious in others cannot find a method for controlling food supplies is surely thus. There is no need for a third of the world to be hungry, for a baby to die of starvation every forty-two seconds. But the boundaries drawn around the sub-systems, around each country and around political blocs, are too rigid. In terms of the entropies which system-oriented scientists perforce discuss, these sub-systems operate within virtually adiabatic shells. Hence there is no chance of levelling out food supplies, which constitute the energy of the total system, or (by a mapping) of levelling out human happiness and human misery. Nor is there any obvious political technique by which a Stephenson Lecturer can propose to start engineering with these conventional packages. In national affairs, there is. Let us consider some examples.

It is by now a platitude to say that the plan conceived for the future of the railways is probably wrong, but that if it is wrong the fault lies with a Minister and not with the Rail Board. This is said because the railway chiefs were given certain tasks concerned with railway profitability; they were not asked to take into account the integral system of national transportation. Here, I should agree, is a perfect example of what the logician calls *fallacia divisio*: separating components which ought to be kept together. Keeping those components together is indeed a systemic imperative. Where transport is concerned, we have most notably fallen foul of the classical mental discipline which tries to build large systems as aggregates of carefully studied elements. That people should in general be able to get from one place to another is important. But this aim has become subservient to bogus optima, whereby each element of the system must itself be 'economic'. On the railways and in the air-lanes, this criterion has been applied. So far as roads are concerned, attempts are often made to cost the journeys of the private motorist, and to show that it would be cheaper for him to travel by public transport.

Beginning with this case, we see how the systemic law is ignored. If a man lives in circumstances which necessitate his owning a car, then the car is part of his transportation system. To cost a journey which he could have

made by train on the basis that the capital cost of his car ought to be apportioned by mileage to this journey is a silly piece of accounting. He has this car anyway. The cost of his journey includes wear on the car perhaps, as well as running cost; but it certainly does not include a share of capital cost. On this basis, he will prefer to travel by road on economic grounds. Thus begins the destruction of that non-homomorphic model which calculates travel in terms of a fixed price per mile. The cost per mile of any kind of journey depends on the systemic context. It follows that the prices charged per mile by transport undertakings ought not to be invariant, as they basically are. For example, since the profitability of an air journey depends on the proportion of seats occupied, and since potential passengers are to some extent motivated by economic considerations, it follows that the price per seat for a given journey should vary with the bookings made. Thus the price paid for an air ticket reserved months in advance would include a component for the value to the passenger of a guaranteed seat. As the time of departure approaches, the price for a seat should fall. A passenger prepared to risk making no flight in exchange for a cheaper ticket would bring the plane's occupancy to an economic level. Note that a continuously computed fare based on these factors would at last begin to engineer with the uncertainty of demand, founding itself on high-variety systemic interactions between the air service and need, and between the air service and competition.

This kind of approach takes note of how the world is; it begins to construct a homomorphic model which can be used for deliberative control. At present, our controls are attempted impositions of rules which do not pay off because they struggle against the tide of entropy. In such cases the proper resort of management is to engineer with the structure of the system, until the entropies created in interaction with the world yield what the airline wants, namely, a profit. A similar argument may be applied to the railways, which have tried by advertising to condition the passenger to believe that 'it is quicker by rail'. Often, it is not quicker. Often, the potential passenger is less impressed by speed than by comfort, cleanliness and a sense of privacy. His selection entropies may then be drifting in a direction that does not conform to the systemic reference frame set up by the railway management. The battle for custom is then lost. If a passenger prefers to be fussed over by a pretty air hostess than insulted by a ticket collector, it is no good protesting that he should have more sense: and the best conclusion is not necessarily to close the railway line. It may be to abandon the attempt to match a high-variety demand with a low-variety service. Not even a monopoly can force through the repeal of the law of requisite variety.

Nor, indeed, can a whole powerful ministry repeal that law. The task of controlling road traffic, when attempted by policemen or by local regulators such as traffic lights, is a high-variety task unsuccessfully handled by low-variety control devices. It is quite obvious that requisite variety cannot be obtained to handle a problem of the magnitude now made manifest without massive sensory input to large-scale computing engines. Yet the use of computers is regarded, at worst, as a novel gimmick; and, at best, as an expensive innovation which perhaps must come as part of a technological upsurge. We never see the argument, based on fundamental thinking, that there are systemic imperatives which can be analysed and must be met. It is not surprising, then, that we see no attempt to derive the homomorphic model of national transportation which would serve as the basis for well-informed research into the deliberative control of movement. Such a model must be global, following the principles adduced in the preceding section. Ideally, we should use satellites to photograph the ebb and flow of traffic, in order to obtain the systemic conspectus that we need. There are less

ambitious ways of doing so. But the London Traffic Survey does not even have this aim. It represents the old-fashioned, non-systemic approach of trying to understand the elemental components of the system. Life is too short.

The result, moreover, is that we do not begin to approach the cybernetic problems of traffic control which really are important. If we had a homomorphic model of the interactions of sub-systems of traffic, we could begin to work on the serious issues that affect the dynamics of all big systems. (So far we have not discussed dynamics at all, only the structural aspects of systemic control.) Now the great problem in cybernetic dynamics is this. Every sub-system, however defined, is itself seeking a local stability. The big system as a whole seeks stability in terms of such local equilibria. But the homomorphic model of the big system, as expressed through the interaction of sub-systems, is difficult to express in homogeneous terms. The reason is timing. If a sub-system is to be regarded as having an input which is the output of another sub-system, then it is vital that the relaxation time be consonant with the periodicity of the perturbations arising from the input sub-system. Otherwise, the receiving sub-system will remain in perpetual uncontrolled oscillation. Moreover, from the point of view of deliberative control considered as an inverse mapping of the model, there is a problem of scale. One sub-system will see an interconnected sub-system as pumping variables into its equations of motion; another will see the same input as setting its basic parameters. Which is which will depend on the relative relaxation times of the receiving sub-system to the two input sub-systems. There is no need, surely, to press these problems to an audience of engineers. The point is that we have no idea how to handle them, because we have not even recognized that they exist, because we have not even begun to think out the model that reflects them.

They are, nevertheless, the problems which have to be solved: and if they exist for traffic management, they exist for economic management too. Moreover, if it is wrong to cut up the transportation system into separate units, it is wrong to cut up the national fuel system into separate units too. Who is there in the country at all who understands the systemic interaction between coal and gas and electricity and oil and atomic power? No one, so far as can be discovered, has begun to consider the homomorphic mapping of this integral whole. The examples are capable of indefinite extension. They seem to indicate a wholesale failure to understand anything at all about the prerogatives of systems. I hope it will now be appreciated why such care was taken to expound a methodology which can at least begin to discuss such matters, and why it is important to see that there has to be a reversal of the classical trend whereby science advances from the element to the system. It is because we have always done this, I repeat, that we have not to this day encompassed the really big system at all.

This difference of approach may be examined in the context of another big system which is particularly important to us all, namely, technical education. The future of this system and the demand on it were investigated in a famous White Paper, it may be recalled. The method of this enquiry, it will be no surprise to recollect, was to build up the 1970 requirement for technologists from the atomic components of employment as it existed in the past. There was no attempt to assess systemic interaction, nor the systemic trajectories of the future. In another paper<sup>4</sup> I have tried to expose the fault in this enquiry, and to show how the cybernetician would approach the task of modelling the actual control mechanisms involved.

There is one last point to make about the prerogatives of systems in the world at large, and it is this: Because of the habit of dividing, for administrative convenience, what should be kept together, we often identify as special

to a part what is really a function of the whole. This causes us to try to measure, as a sub-systemic variable, some factor which might best be understood as a behavioural (that is, output) characteristic of the entire big system. An example which springs to mind from recent work concerns marketing. Everyone who spends money on sales promotion would like a measure of advertising effectiveness. This is, inevitably, sought in the change in sales value that follows in the wake of a campaign. But it is notoriously difficult to measure this change and to relate it to the appropriation—because of systemic interaction. There are time-lags, competitive effects, changes in conditions, and so on. It has become increasingly likely, to me, that the desired measure is not only impossible to make but actually invalid. The flavour of the argument, which cannot be set out here at length, is obtained by asking where in the engine of a car is to be found the vehicle's speed.

This sort of consideration can be contemplated with competence from the vantage point of an effective homomorphic model alone. For example, mention has already been made of the National Health Service. This centres on a system of patients and doctors interacting, each set providing the other with requisite variety. But there are several sub-systems interlinked with this one, and interpenetrating with it element by element. Two most notable such sub-systems are the regional hospital organizations and the pharmaceutical profession. All these sub-systems seem often to be uncoupled in the administrative and indeed the professional mind. Then the interesting question is how to resolve such a problem as the appropriate payment of all concerned. Here perhaps is another example of a global behavioural characteristic, masquerading as an entire set of sub-systemic variables. Certainly it is a problem for engineering in large systems to resolve, rather than a matter of local accountancy.

### Systemic Control in 'The Flesh'

There are various levels at which we can examine the relevance of systemic laws to animate systems, considered as distinct from the world that is not aware. If we chose to discuss the individual living creature, we should find many examples to enlarge our cybernetic understanding. For *Amoeba proteus* and *Homo sapiens* have this in common: they are both very big systems compounded of sub-systems, and their character is systemic or it is nothing. Indeed, if we nominate viability as the objective of any organism, whether animate or pseudo-animate (as a firm or an economy), it is natural to turn to biology for advice. Cybernetics has sprung from biology, and has quickly involved physics and engineering, rather than the reverse, for perfectly sensible reasons. It is wise not to forget this, nor to ignore its lessons.

But the example of the operation of systemic laws 'in the flesh' that I shall take here comes from a different level of viable organization. I want to talk about the process of decision in a management group. Now decision theory, so-called, we have; it is an investigation appropriate to mathematical statistics. But decision theory assumes a uni-dimensional model of the world; it says that we know the terms in which we should rightly talk, and that we know the interactions that are important; it is not systemic. The process of decision in a management group is, on the contrary, systemic in character. The reason why it often takes many years to reach a complicated decision is because this is not understood.

Consider, then, such a decision. For example, where, and when, and how should the country add to its steel-making capacity by building a new plant? All manner of people will have views on this, arguing from every sort of expertise. The management problem is to find coherence in the spate of advice. Some of it will be factual; some of it will be inspirational masquerading as factual;

most of it will be contingently factual—that is, 'what I am saying is true, if something else is true, but not absolutely'. It is the contingent advice which specifies the system of decision; but unfortunately most of it is not recognized as contingent. It is here, then, that operational research is needed, so that the decision space and its configurations may be rightly understood. But operational research will not take this decision. It will be taken by a large number of people, each of whom is guaranteeing some sub-decision of the whole. The control problem for the highest authority is to monitor the decision-taking procedure to which all the sub-deciders are contributing.

The classical approach to this situation is to regard a very minor sub-decision as a basic component, and to build up a highly complex total decision from these elements. Hence some junior metallurgist somewhere may declare it obvious that a metallurgical reaction is best obtainable in a certain way, and begin to dictate the whole technology to be used. An economist looks at the siting problem in terms of the technology he knows about; and so on. But, according to the arguments in this article, we should not build up a very complicated specification from single components of decision. There is another way of looking at the matter. We do not really start with a set of elemental propositions, but with an infinitely large number of high-variety, integral alternatives. We do not really finish with a highly complicated specification for action, but with a unique integral answer. So the decision-taking procedure is not a process of building up more and more variety, but of eliminating more and more uncertainty. How can this procedure best be controlled?

We said that the decision space had to be defined and that it is composed of possible answers. That is to say, every alternative integral answer might be considered as a small square. The decision space would then be the totality of these alternatives—say, a million small squares. For convenience, we might consider them as arranged in a square array, or matrix. This decision space will be ranged over by any decision procedure, in a hunt for the right answer. A management group normally undertakes the task as a heuristic search, which goes on by elimination. The average number of steps taken before the right answer is recognized is evidently half a million, since there is no reason why the right small square should be encountered either sooner or later than any other. True, sub-sets of small squares may be eliminated at once if they share a recognized characteristic regarded as damning; on the other hand, there may be a great deal of wasteful hunting back and forth between two or more sub-sets of small squares, each of which looks as if it might include the right answer. Note that this procedure is precisely obeying the control law of requisite variety. The variety of the decision space (a million alternatives) is matched by a control process organized to examine (if necessary) a million squares.

However: the natural variety proliferation of the world can be matched by variety generation—which I define as a deliberative control device. The decision space in our example is a square array. If we can identify the co-ordinates of this matrix as logical variables, then we can specify any small square (including the right answer) as a logical couple. To do so, we must search the co-ordinates. But the variety of each co-ordinate is 1,000; so the search space is 2,000 (instead of 1,000,000), and the expectation is that we find the answer in 1,000 steps instead of in 500,000. Thus the variety generator fulfils the law of requisite variety (since it has the selection power to discriminate between all the alternatives) but is a deliberative controller five hundred times as efficient as the natural controller.

All this is said to demonstrate the point. In practice, there is no reason why the decision space should be two-dimensional. Indeed, if a given decision had only two

logical variables, it would not be a difficult decision. Then it has  $n$  logical variables, and the decision space is an  $n$ -dimensional space. Then the variety generator is yet more efficient. For the expectation that a set of integral alternative answers of high variety  $V$  will yield up the wanted answer by a general search is  $\frac{1}{2}V$ . Whereas the expectation for an  $n$ -dimensioned search with variety generators is  $n/2.V^{1/n}$ . We have found in principle a method of dealing with large-scale decisions which capitalizes on the systemic structure of the problem. It is just not true that decision-takers normally do take this advantage, by some analogue of this algorithm, as empirical research into actual decisions reveals. But it remains to show how we shall take advantage of it in practice.

First of all, it is necessary to identify the logical variables which are relevant. That is to say, we need to know all the dimensions of the decision: what sorts of things have to be specified to make the decision definite. This process is not one of listing all the statistical variables which affect the magnitudes eventually to be used: that side of the job is done by applied mathematics. We want to know what factors must be accounted for before the decision counts as a decision. The steelworks decision, for example, is not specified unless it includes the location of the works, its output of ingot tons, its range of products, and so on. These are the logical variables. The systemic interaction of these variables defines the configuration and dimensionality of the decision space. The statistical variables will eventually determine the optimal *modus operandi* of the steelworks decided on.

The number of logical variables is  $n$ , that is the dimensionality of the decision space. But the variety-generator notion enables us to observe that the  $n$ -space involved is not just a square, nor a cube, nor a hypercube: it has a configuration. Suppose, for example, that it is sub-decided for sufficiently powerful reasons to have a steelworks of given ingot tonnage, or at any rate within some range of tonnages. This automatically delimits a range of reasonable costs, a collection of possible sites, and so on. We do not yet know what the elements of these sub-groups are; but we can see that the decision space is inwardly contorted in various ways. There exist logical inferences, which we have not worked out, for any combination of logical values that may be fixed for any of the logical variables. In that case we must try to express the decision space in terms of its logical variables to give structure to the systemic configuration which the real world tends to proliferate.

The way to do this is through symbolic logic. This is the language of science for handling relatedness: conjunctions and disjunctions, implications and inclusions. The decision we are after has a known number of logical dimensions, for we have listed them. The systemic structure of the decision will be given by a logical formula stating how the logical variables are interrelated. Now this is a model in the sense defined. It requires a mapping of the way the external world works in relation to this decision. We have its dimensionality; we have its configuration. Next, we must measure its variety. In fact, this is not too difficult. Some logical variables are binary, in which event they offer a single alternative—a one-bit decision. For example, the steelworks must either be integrated with an ironworks or not. Other logical variables may propose a group of choices. For example, there is a finite number of steel-making processes between which, or between combinations of which, a decision must be taken. Suppose that, in a given case, there are eight choices. The variety of this decision is 8, not 2. This is a three-bit decision: it is composed of three binary decisions:  $2^3 = 8$ .

We have now discovered how to measure the variety of the decision, which is to say the uncertainty which has to be removed in searching for the completed specification. The measure is, of course, an entropy; not a thermodynamic entropy, nor the entropy met with in statistical

mechanics, but an informational entropy—an entropy of selection. But, however we view it, the statistic that computes its value is the same. It is:  $H = - \sum p_i \log_2 p_i$ , where  $p_i$  is the probability of the  $i$ th choice. (We can ignore Boltzmann's constant in this application.) For every logical variable in the logical formula, we must compute this entropy.

In the case where the choice is a straight alternative between equiprobable outcomes, the entropy is  $H = -(0.5 \log_2 0.5) - (0.5 \log_2 0.5) = 1$ . This is the classic one-bit decision, and it shows why we are accustomed in cybernetics to use logarithms to the base 2: the answer is measured in the units of information theory, namely, bits. Now, in any application, there may be reasons why one alternative is more probable than another, and this will disbalance the equation. For example, if a committee of ten people is divided nine-to-one on the first showing of hands, the uncertainty to be resolved is less than one bit: If we wish, we may use this kind of fact as a measure of probability. Thus:  $H = -(0.1 \log_2 0.1) - (0.9 \log_2 0.9) = 0.469$  bits. But in general, we may consider that all alternative choices are nominated as equally probable. In the case that there are  $m$  alternatives, the equation is  $H = -m \cdot 1/m \log_2 1/m = \log_2 m$ , which is, of course, simple to compute.

By summing the selection entropies appropriate to each logical variable, we obtain a measure of the uncertainty that has to be eliminated in reaching the decision. This quantified formula is now a control device of requisite—and measured—variety. For any attempted specification of the decision, put forward by any party to it, has a certain entropy that can be computed; and the difference between this number and the number of the logical formula measures directly the inadequacy of the proposed answer. Moreover, if we start with a given level of uncertainty, we may progress our decision-taking by computing the uncertainty eliminated by any agreed sub-decision. Evidently, when all the uncertainty has been eliminated, the entropy is zero—because the probability that this is indeed the answer is unity. In other words, the decision has been taken.

In practice, the rate at which uncertainty is eliminated by a decision procedure will be some kind of negative exponential decay function. Empirical research will establish the family of curves which it is appropriate to use as control optima, and fiducial limits can be set up. Then we have an error-controlled feed-back loop with which to monitor the progress of the decision-taking. In a particular sphere of decision, moreover, particular clues to the uncontrolled situation will emerge. For example, whatever the decay function for uncertainty, it will surely be monotonic-decreasing. Hence if, in the course of plotting the progress of the decision-taking, a sudden upsurge in the graph should occur, it is clear that something has gone wrong. Uncertainty is being imported into the system. This will usually be due to an unacknowledged change in the objectives of the decision. It is clear evidence that the logical formula ought to be re-examined, and perhaps subdivided. Here again is one of those control devices which operate on unanalysed systemic blocs, rather than on elemental components.

This procedure, which is here made public for the first time, seems to be a powerful tool. It is simple to use, though difficult to understand for anyone who has not undertaken the preliminary methodological thinking given in this paper. Its particular merit, I believe, is its capability to quantify a logical structure. Hitherto, it has been virtually impossible to disclose a mode of inference which would couple together, in one technique, the power of logic to specify structure (which is much greater than that of mathematics) and the power of number to compute comparisons and the parameters of control (which is much greater than that of logic). It is a tool that has special value in the context of national decisions, such as those discussed in the preceding section; because the

specification of each such decision is so great, and the parties to it so numerous and so dissociated organizationally.

### Systemic Control in 'The Metal'

Having discussed, however cursorily, the relevance of the pervasive notion of system and its natural laws to the world and the flesh, we finally reach the metal. The metal stands for machinery, for devices, for artefacts built by man. Here, surely, we do understand the laws of system; here, one might hope, there is nothing to say.

Unfortunately, this is not the case. Where relatively small systems are concerned, the laws of system as understood by control engineering are happily ascendant. But we make big systems, by the criteria used before, in hardware too. In particular, we make computers, and we sponsor automation. It would be uncouth to repeat now all that I have so often said and written before on these topics<sup>5</sup>. But a few points ought to be made in the terms established by this text.

First, a system of automation is a deliberative control, that is, as has been stated, an inverse mapping of an  $M$  on to an  $A$ . It is vital that the laws of requisite variety be upheld; yet no automatic controller yet devised begins to match the variety of an ordinary works. Consequently, the Buddhist principle of control has generally been applied. It is the central, perhaps the only, idea of Buddhism that since we can never reach our targets of desire (and are thus condemned to frustration) we should alter those targets to equate with whatever we in fact attain. If what we are and enjoy becomes our target, behold, we have attained it after all. This is exceedingly good cybernetics; requisite variety is ensured, not by generating variety in our lives, but by eliminating variety in our ambitions. It seems to me that our notion of automation depends on this rule: the factory must behave in the way we have engineered to control it.

The result of this is that automation has been applied only to relatively straightforward, mass production situations—which are low-variety worlds. The jobbing works, on which the British economy largely depends, has so far been immune—*qua* big system. Sub-systems have been automated, it is true; and the computer-controlled machine tool is an example. But if we rightly understand and apply the systemic laws of cybernetics, it will not prove impossible to make automation much more general. The secret is, of course, to use computers as variety generators. Operational research does precisely this with its simulations; but engineering seems to think more in terms of variety reduction.

Thus we have the spectacle of the logical space of a general purpose computer programmed down to low-variety control, as, for example, in its application to the cut-up line of a rolling mill. This seems to be as wasteful of decision-taking capacity as is the programming down of a high-variety human being to being a machine-minder. There are no ethical objections in the former case as there are in the latter; but there are much stronger economic objections. These are the source of the marginal pay-off from computer applications in real time, which in my opinion is in turn a major cause of the slow advance of automation itself. The on-line control computer ought to be sensorily coupled to events in real time, and ought to have a motor output similarly coupled. But in between it ought to be uncoupled to a greater extent than is required to undertake a few simple-minded calculations on its inputs. In particular, it should have the facility to simulate the outcomes of possible decisions and to choose between them. This is not at all difficult to do; it is not even difficult in principle to equip the machine with a learning facility through which to profit from its own experience. The trouble is that managements do not commission such applications, and engineers do not offer to make them. The reason is, I strongly urge, not the imagined difficulty, but a very real insensitivity

to the systemic rules of the game. As we are trained in the scientific methodology of analysis rather than synthesis, so we are trained in the Buddhist principle of control. We are variety murderers to a man.

An interesting example of this contention is found in the machine translation of language. A language is a high-variety system *par excellence*. The history of machine translation shows how science ignored this fact, and set out to translate automatically using low-variety control. It obtained, with chagrin but quite predictably, very bad translations. But a start had been made. Gradually the research began to acquire for the automatic translator some of the variety it had manifestly required from the outset. Crude syntactical paradigms were replaced by more elaborate ones; stored vocabularies grew. But the methodology is the old familiar one. We are aiming to reach requisite variety by the exhaustive enumeration of possible states, and we are still a long way off. Yet the computer as such is by no means short of variety; the inadequacy has been in the variety of the structuring of the decision space. We are not using variety generators, once again.

Surely the clue to this problem is the way in which people learn to translate (note the word 'learn'). We do not set out to programme children to be good translators. The trick is, rather, to give them a rudimentary grammar and vocabulary with which they are encouraged to experiment. They proceed to generate variety all right; the only trouble is that the output is unacceptable. So we monitor the output, using a skilled linguist (called teacher), who himself has requisite variety. He observes the defects in the homomorphic mapping of acceptable language on to the child's language. He then corrects the child by reinforcing successes with rewards and damping down failures with reproof. In systemic terms he uses what I have called the algedonic (pleasure/pain) loop. It is not difficult to devise an artefact of this loop inside a computer: all one needs is a simple conditional probability model to supply the criterion of retrieval. Instead of the rather naïve notion that a stored linguistic association is either present or absent, we want the stored material to be more or less likely to emerge—in accordance with a balance of systemically connected probabilities, gained by experience, that the answer will be praised or blamed.

I do not think we should be too diffident in seeking to imitate in such ways what are apparently human prerogatives, for they may be nothing more than systemic prerogatives—which is what this lecture is about. Before becoming emotional about words such as 'think' and 'create' it is well to define in behavioural terms what counts as thinking or creating. If this proves to be possible, it seems to me inevitable that science and engineering between them can devise a machine with comparable behavioural characteristics. This is all we need. It is interesting to ask whether such machines are 'really' thinking and creating, and if so how, and if so whether human beings do the job in the same way or some other. But to declare that machines can think, or that machines cannot think, seems as meaningless as it is pointless. I should refuse to mount the scaffold on behalf of any such proposition. But bear this in mind: whatever we may reckon as to genuinely human prerogatives, and as to the possibly divine nature of man, what we see men actually do is organized to be done by their brains: and the brain itself is a control machine.

A good and a final example of what I mean concerns the trick of procuring arbitrarily reliable outputs from a machine with arbitrarily unreliable components. Considered in engineering terms, the brain is a frighteningly defective apparatus, and yet it serves us well. It was because John von Neumann posed the question: "How do we retain any semblance of humanity when we have had too much to drink?" that cybernetics found out how the brain works this apparently impossible trick. As is now quite generally known, the answer is that it generates

the requisite variety both structurally and operationally through redundancy: redundant nodes, redundant channels, redundant control complexes, redundant calculations. We have the theorems by which all this works; we even have a special logic of neural nets by which to describe it. But, again, engineers do not want to use all this knowledge. They have been brought up to believe that components ought to be reliable, and they design as if they were reliable. But no one has ever seen an actual component that did not have a measurable, finite probability of failure: and in a big system, a complex ensemble of components, these probabilities are multiplicative.

The result is that we refuse to send one redundantly controlled rocket to the Moon to make a few observations; we cannot afford to accelerate 'unnecessary' componentry to escape velocities. It is apparently better to fire six rockets, beautifully engineered and shorn of redundancy, none of which gets there. Again, we cannot afford the high cost of redundancy in a railway signalling system. After all, if perchance it should go wrong, the accident inspector will declare that it was 'one of those things'—a one-in-a-million chance. Personally, I regard myself as one of several million passengers; and my ghost would doubtless take a poor view of these odds. Yet again, then, we cannot bear to tell industrialists that they should consider installing redundant automation, because the expense might frighten them off the project. We prefer that they should refuse to accept automation on the grounds that it might go wrong.

It does not, in fact, seem to be totally ludicrous that we should be thinking in terms of a new kind of systems engineering, in the metal—as in the world and the flesh. It would be an engineering appropriate to big systems, aimed at providing requisite variety for control, equipped with variety generators, redundant circuitry, and an interpenetrative connectivity. Consider the following vision. Here is a vast plant, a huge, complex interacting system. Its engineers have built control equipment into it, of a subtle cybernetic kind. The plant is therefore self-regulatory (we know that trick). It is to some extent self-organizing (we begin to know this trick too). The plant is adaptive to environmental changes (we have discussed how this could be done through algedonics). But the built-in control systems keep going wrong. The teeth of the cogs drop out, the transistors fail, wires come adrift, whole packages burn out. The engineers, however, have seen all this happen in the brain. They have noted that brains do not continually 'go off the air' for maintenance: and so they have copied the brain's trick for handling unreliability, no longer complaining that things sometimes go wrong when manifestly they cannot always go right.

This works continues to work, despite all. It is not attended by an army of white-coated technicians armed with soldering irons, as some prophets have supposed. For the built-in control equipment is designed to outlast the plant. Do not say this is impossible; you and I are the evidence that it is possible. Do not say that it is impracticable; we have not even tried, and the principles are known. Say, if you must, that you are not going to do it, that you cannot afford it, or that it is time to go home; let us know where the onus lies.

There are systemic laws to apply, which could change the face of Britain—as George Stephenson once changed it. Twenty years before the *Rocket* ran that illustrious man nearly dug out the brain drain; for he was disheartened, and contemplated emigration. Some of us here have done the same. May we instead learn from his example, and see the visions through.

## SHORTAGE OF SCIENCE APPLICANTS TO UNIVERSITIES\*

By SIR EDWARD APPLETON, G.B.E., K.C.B., F.R.S.

Principal and Vice-chancellor of the University of Edinburgh

THAT members of the conference on the above subject have responded to an invitation to attend shows that they, like those of us in the University of Edinburgh, really care about what ultimately happens to those young people who pass through the hands of all of us. It also shows that we care that our institutions of education should provide, in sufficient numbers, the kinds of men and women who can promote the welfare and growth of the British economy. Now since the British economy is that of an industrialized society, in which we depend, in large measure, on the application of science, by way of technology, for industrial strength and expansion, we are vitally concerned with supplying that society with both managers and workers trained in science and technology. And when I mention people trained in science and technology I include mathematicians as well, so long as they are mathematicians who display vigour, even sometimes at the expense of complete rigour, in their approach to their subject.

Now our supply of people capable of adding to our scientific capital, by way of research, depends on education. Similarly, our supply of people capable of using technology, and of adding to it by design and development, also depends on education. But the education of people of the kind I have mentioned is conducted in two tiers, school and university, and both are represented at this conference.

Now it would be quite wrong of me to attempt to compare these two tiers of education—school and university—in importance. Yet I venture to point out that it is often at school that a student's interest in science is engaged and his enthusiasm for it fostered. Moreover, I imagine that most people are attending the conference because of the influence of some particular teacher in this respect. I certainly know that this applies to me.

Now there are certain careers for which it does not matter much what courses have been pursued at the university. We can all agree that one essential function of university education is to develop the student's capacity to learn, to understand and to think on his own. For that purpose alone the degree course taken is often said to be immaterial. Now this may be all very well for people who join, say, the administrative grades of the higher Civil Service, for they become trained on the job, so to speak. But it is quite different with scientists, technologists and mathematicians who join the Scientific Civil Service, or industry, as specialists. They cannot learn the elements of their trade on the job. They must be soundly versed in fundamentals at the start, even if, as happens frequently in industry, they require further initiation in the particular technology which is the concern of the firm they serve.

Now, with our present gearing of the two tiers of education, the decision that an individual is going to pursue a scientific or mathematical career has to be taken at school; and, with things as they are, there is something wrong, from the point of view of the country's needs, at the school stage of decision. Not enough people are deciding to prepare for a university career in scientific subjects the mathematical content of which is high; and not enough young people are deciding, on university entry, to choose the applied sciences as distinct from the pure sciences.

So one of the questions for us to-day is this: "How does it come about that engineering is relatively so unpopular?" Some people have said that one reason for this is that engineering is not a school subject—generally, that is. I put the question recently to the president of one of the engineering institutions—the big three: "Should Engineering be a school subject?" and his answer was: "Certainly not. Concentration there should be on mathematics and the basic physical sciences". From the school side it is said that university engineering is too difficult: the failure rate is high and this has seeped through to the schools. The same is said of university mathematics courses. "If you want a degree take something else."

Now this leads me on to observe that one effect of the publication of the Robbins Report has been to infect people with what I may call 'degree worship'. Universities were at one time enjoined by the University Grants Committee to attempt to increase their first-year science entries at twice the rate at which they increased their arts entries. But all that has now gone since the publication of the Robbins Report.

The provision of a university education is taken as an act of social justice, and universities must do the best they can to meet 'consumers' choice'. There are two consequences here. Young people tend to choose subjects for their degree which interest them—which is, at least, understandable. But what is really unfortunate is that many of them, with a degree alone in mind, choose subjects which they deem to be easy ones, regardless of the effect of this on their career prospects after leaving the university.

Now this situation of *laissez faire* cannot, in the country's interests, be allowed to continue. We must bring home to school pupils, to university students, that in so many cases the choice of leaving examination subjects at school, and the choice of a degree course at the university, will determine their prospects of employment hereafter.

To help young people, as well as parents and school and university teachers, there is a need for forecasts of future employment prospects. This applies especially to science and technology if we are to stress the attractions of careers in these subjects. Something of the kind is being done already by one or two professional institutions. But there is need for an official, central, employment forecasting agency to keep such matters under continuous review.

Take, for example, the newly instituted Ministry of Technology. Its objectives have been described but not, as yet, the methods whereby those objectives will be achieved. Exhortations from Whitehall will be useless unless someone, Government or industry, can specify the methods by which innovation can bring about industrial expansion and can indicate, to institutions of higher and technical education, the requirements in terms of scientific and technological man-power which these will entail.

Now I have only two matters further to mention. They are both concerned with what I have called the gearing between school and university. I have received evidence from some parents that, in certain cases, school pupils are entered for higher subjects in their leaving examinations merely because they are good at them, and can therefore swell the number of passes which the school can claim; and this is sometimes done without regard to the requirements of university entry and the pupils' future career.

\* Substance of the opening address delivered at a conference on the "Shortage of Science Applicants to Universities" held in the University of Edinburgh on December 12.

The other matter arises from the shortage of sixth-form scientific and mathematical teachers; and is expressed simply in the question: "Can the university take over some of the elementary science and mathematical teaching which is at present in the care of the school?"

We have all heard much about the difficulties impeding science teaching in schools—shortage of staff, lack of space and equipment. I appreciate that one reason for

the shortage of science and mathematical teachers is that there are, nowadays, so many other attractive careers, outside the schools, which are open to them. Then there is the unfortunate fact that many young graduates have come to regard teaching as a disgruntled profession and therefore an uninviting one. It may seem like that from the newspapers; it does not seem like that when you talk to a science master about his own pupils and their prospects.

## NEWS and VIEWS

### Engineering in the Massachusetts Institute of Technology: Prof. J. C. Keck

DR. JAMES C. KECK, an authority on high-temperature gases and plasmas, has been appointed, as from July 1, a Ford professor of engineering at the Massachusetts Institute of Technology, where he will establish a Laboratory for Atomic and Molecular Kinetics within the Institute's School of Engineering. Dr. Keck is at present a principal scientist at the AVCO Corporation's Everett Research Laboratory, Everett, Mass. The new Laboratory will be established within the Department of Mechanical Engineering, but its facilities will be available for teaching and research to staff and students from all engineering departments. Its main aim will be the application of basic knowledge gained from studies on the structure and behaviour of atoms and molecules to applied engineering problems of present-day interest, such as re-entry aerodynamics, heat-shield design, power generation and conversion, rocket propulsion, etc. Dr. Keck's own scientific interest in recent years has centred on basic studies of gases that are heated by shock waves, with particular reference to chemical reactions, radiation phenomena, and ionization processes that occur at the atomic and molecular levels in such gases. He was deputy director of the AVCO Everett Laboratory from 1960 until 1963 and has been chairman of the Laboratory's Atomic Physics Committee since joining AVCO in 1955. Dr. Keck gained a B.A. degree in physics at Cornell University in 1947 and a Ph.D. in physics, also from Cornell, in 1951. He was a research associate at Cornell in 1951–52 and a Senior Research Fellow at the California Institute of Technology from 1952 until 1955. At both institutions, he worked on problems in nuclear physics, particularly photonuclear reactions, using high-energy synchrotrons.

### Computing in the University of Leeds and Directorship of the Electronic Computing Laboratory: Prof. G. B. Cook

DR. G. B. COOK, senior lecturer in applied mathematics in the University of Leeds, has been appointed professor of computing in the Department of Mathematics and director of the Electronic Computing Laboratory in the University. Dr. Cook was educated at Owen's School and Selwyn College, Cambridge. He read the Natural Sciences Tripos Parts I and II and the Mathematical Tripos Part III, in which he shared the Mayhew Prize. He remained at Cambridge during the period 1950–53 as a research student in the Department of Theoretical Chemistry and the Mathematical Laboratory, and he was awarded the degree of D.Phil. in 1954. From 1953 until 1957 he was on the staff of the Basic Research Division of the Royal Armament Research and Development Establishment at Fort Halstead. He went to the University of Leeds in 1957 as lecturer in electronic computing and was promoted to the directorship of the Computing Laboratory in 1960. He relinquished this post to become senior lecturer in applied mathematics in October 1964. During his time in Leeds, he has had a close association with

Lyddon Hall, having been a sub-warden for part of the period. Dr. Cook has served on committees of the Scientific Advisory Council and of the British Standards Institution. Since 1963 he has been a member of the Council and of the Education Committee of the British Computer Society. Recently he was appointed a member of the Church of England Board of Education. He is also a Fellow of the Institute of Mathematics and its Applications and of the Physical Society. His research interests include computational problems in quantum theory and diffusion, and he has published several articles on these subjects.

### Theoretical Chemistry in the University of Bristol: Prof. A. D. Buckingham

DR. A. D. BUCKINGHAM, who has been appointed as the first holder of the new chair of theoretical chemistry at the University of Bristol, graduated in 1951 from the University of Sydney, with first-class honours in chemistry and the University Medal. He obtained his M.Sc., under Prof. Le Fèvre, before proceeding to Cambridge on a Shell scholarship, to work with Dr. J. A. Pople. He moved to Oxford in 1955 on an 1851 senior studentship and, in 1957, became a student of Christ Church and a University demonstrator in the Inorganic Chemistry Laboratory. His early association with Le Fèvre gave him a lasting interest in electromagnetic polarization phenomena. At Oxford he has carried out and directed both theoretical researches and experimental investigations on the optical, electrical and magnetic properties of molecules, and on intermolecular forces. Dr. Buckingham gave the Tilden Lecture of the Chemical Society for 1964, has served as visiting lecturer at Harvard (1961) and is shortly to spend a period at Princeton. As well as being a distinguished theoretician, he is a cricketer of some stature; he has played for the University of Sydney, New South Wales (although not in the Sheffield Shield series), the University of Cambridge and, for the past few years, in the Duke of Norfolk's XI at Arundel.

### Agricultural Economics in the University of Manchester: Prof. W. J. Thomas

MR. W. J. THOMAS, reader in agricultural economics in the University of Manchester, has been appointed to a newly established chair of agricultural economics as from January 1. Mr. Thomas was educated at St. David's College School, Lampeter, and the University College of Wales, Aberystwyth. In 1939 he was awarded a degree of B.Sc.(Wales) in agriculture, and in 1940 the honours degree of B.Sc. in economics with agricultural economics. After graduation he joined the staff of the Department of Agricultural Economics at Aberystwyth and was awarded the degree of M.Sc.(Wales) in 1945. During this period he also worked on the Scientific Food Committee and on several regional and national committees connected with the war effort. From 1946 until 1949 he was senior agricultural economist in the Ministry of Agriculture in London, the duties of this post involving the collection and collation of material relating to the economic position

of the agricultural industry and the use of this material for price review and agricultural policy. In 1949 he was appointed lecturer in agricultural economics at the University of Leeds, a post which he held until 1953 when he was appointed reader in agricultural economics and head of the Department at the University of Manchester. His own research work has been mainly in the field of agricultural policy and on the economics of grass-land production and utilization. He has served on various national and international committees on agricultural problems.

### Vulcain Reactor

IN reply to questions in the House of Commons on December 22, the Joint Under-Secretary of State for Education and Science, Mr. J. Boyden, said that basic engineering and physical work in the research and development programme for the *Vulcain* reactor was now also complete, and a *Vulcain*-type core would be loaded in the Belgian experimental reactor *BR3* in mid-1965 for irradiation to high burn-up. The cost to the Atomic Energy Authority so far was about £1.6 million. The decision to proceed with a prototype fast-breeder reactor must await the outcome of the present development programme based on the experimental reactor at Dounreay and particularly on the design of the fuel.

### The Museum of London Bill

AT the Committee Stage of the Museum of London Bill in the House of Lords on December 21 and in answer to questions from Lord Chorley and Lord Airedale regarding the position of staff transferred from Guildhall Museum and the London Museum, Lord Champion confirmed his assurance that there would be no down-grading of staff transferred from either Museum, and added that the Government would always be prepared to meet representatives of the staff associations to consider these matters. It was inevitable and natural that the terms and conditions of service of the staff of the new Museum should be nearer to local government than to Civil Service practice. The whole question had already been carefully considered, but final decisions could not be taken until the Bill became law and the Board of Governors was finally appointed. Fair and attractive terms would be offered to the staff and these terms would be maintained fair and attractive. There were at present about 70 staff in the London Museum and only seven in Guildhall Museum. While it was accepted that there must be negotiating machinery, it did not appear appropriate to insert a clause making arrangements for negotiation and arbitration statutory. (See also p. 237 of this issue of *Nature*.)

### Improvement in the Status of Technology

IN a written answer in the House of Commons on December 23, the Secretary of State for Education and Science, Mr. M. Stewart, said that, in accordance with the recommendations of the Interdepartmental Committee on Improvement in the Status of Technology, a working party had been set up under his Department's chairmanship, on which the Departments were represented and the Joint Council of Engineering Institutions had been represented at recent meetings. The working party would rely chiefly on continuing to stimulate the interest of the Press and television, and there were close consultations between the working party and television authorities, who were responding to the need for programmes of technological interest. A programme of special Government publicity, prepared with the aid of the Central Office of Information, would include films, exhibitions and publications, and an exhibition on the theme of 'Applied Science' would be held at the end of December in conjunction with the annual conference of the Association for Science Education at the Imperial College of

Science and Technology, South Kensington. The working party was reconsidering the Inter-Departmental Committee's recommendations regarding careers advisers in the schools, the provision of career literature and the promotion of films and broadcasts featuring technological subjects. The Committee's report had been considered by the University Grants Committee, which was taking up with the universities those recommendations that affected them, especially the question of flexibility in courses.

### Anglo-Soviet Co-operation in Agricultural Research

AN agreement was signed in London on January 6 giving effect to arrangements for future co-operation between the United Kingdom and the U.S.S.R. in agricultural research. The agreement, which runs for five years initially, provides for: (a) exchange of information and, as appropriate, of scientific material and visits between scientists and institutions of the two countries on some 61 specified research topics under seven general headings—crop production, soil science, plant protection, livestock production, veterinary science, farm mechanization, and water economy; (b) exchange of scientific delegations in 1965; (c) designated 'co-ordinating centres' in each country; (d) a further meeting of experts in London later in the year, and thereafter annual meetings, to keep the working of the agreement under review. At the signing ceremony, the Minister of Agriculture, Fisheries and Food, the Rt. Hon. F. Peart, M.P., paid tribute to his predecessor, Mr. Christopher Soames, who promoted the idea. On behalf of the U.S.S.R., the agreement was signed by the Soviet Ambassador, His Excellency Alexander Soldatov. Speaking to the Soviet delegation, Mr. Peart said: "Her Majesty's Government welcome the agreement we have just signed as a valuable extension of our friendly relations with your Government. It holds out the promise of really useful co-operation in a field where a glance at the agreement itself shows each of our countries has much to offer the other. . . . Our scientists and scientific institutions will, I know, be working very hard to gain the maximum benefit, for both countries, from the agreement, and in doing so they will have at all times the strong support of myself and my colleagues".

### First Report of the Expert Committee on Drug Toxicity

IN August 1962 the Association of the British Pharmaceutical Industry set up an 'Expert Committee' to advise on certain aspects of the testing of drugs for toxicity. The terms of reference of the Committee were: (1) To review laboratory testing procedures for the assessment of drug toxicity and make recommendations. (2) To make recommendations for promoting the exchange of, and the prompt utilization of, knowledge and experience in this field. (3) To advise on technical and scientific problems of toxicity testing. The first report of the Expert Committee on Drug Toxicity covers only the first term of reference, and does this very adequately (Pp. 24. London: Association of the British Pharmaceutical Industry, 1964). It explains the reasoning behind the toxicity studies which should be carried out before a new substance is given to man, and makes recommendations concerning the tests which should be performed. The report is clear and concise and should be read by everyone who is interested in the toxicity of drugs.

### Industrial Behaviour and Personnel Management

WITH the increasing pace of technological change, it is imperative to make people aware of the need to adapt. It is also necessary to develop specialists in the analysis of the social and psychological problems which accompany technical and economic change. Prof. T. Lupton, Montague Burton professor of industrial relations in the University of Leeds, has put forward his belief in a recent publication from the Institute of Personnel Management that the behavioural sciences are now sufficiently well

developed to make such a specialism possible (*Industrial Behaviour and Personnel Management*. (*Industrial Relations Series*.) By Prof. Tom Lupton. Pp. 59. London: Institute of Personnel Management, 1964. 7s. 6d.). If society as a whole is to reap the benefits of modern technology, social structures must be adapted rapidly and appropriately to meet its demands. Prof. Lupton doubts whether the problems we are facing will yield to "the mixture of philanthropic ideology and administrative technique which are the typical basis of much personnel management at present", and he sees a completely new role for the personnel manager. His booklet should cause many readers to re-examine cherished beliefs, and many personnel managers to consider their adequacy for their existing positions.

### Scientific Research in Schools

THE seventh annual report to the Council of the Royal Society of the Scientific Research in Schools Committee records that 108 science teachers are carrying out investigations with the assistance of the Committee and that the Council's grant of £2,000 has been supplemented by £1,000 from the Atomic Energy Authority for teachers wishing to pursue research of interest to the Authority (Pp. 16. London: The Royal Society, 1964). Further support has been received from 11 industrial concerns. Of the projects, 39 broadly fell into the field of biology, 37 of chemistry, 13 of physics, and 9 of geology. As an experimental extension to encourage the development of applied research in schools, a project was also supported for two school science teachers to join one of the research teams of the Proctor Department of Food and Leather Science, University of Leeds, for 4 weeks during the summer vacation. Besides details of the schools involved and the research projects, the report includes a list of publications in connexion with the projects.

### Choosing a Career

THE series of pamphlets issued by the Central Youth Employment Executive deserves the attention of all young people who have not decided what to do with their lives. The pamphlets cover a wide variety of possible careers, including the various branches of medical and veterinary work, various hospital services and social work, and careers in the arts, in business and in crafts ranging from plumbing to woodwork, stonemasonry and journalism. No. 1 in the series is a general booklet which discusses the points which should be considered before a choice of a career is made. No. 111, *Veterinary Science*, details the preliminary qualifications required for work in this field, and indicates its scope, which includes various kinds of laboratory and field work, as well as veterinary practice. The booklet (Central Youth Employment Executive. *Choice of Careers*, No. 111: *Veterinary Science*. Second edition. Pp. 28+9 photographs. London: H.M. Stationery Office, 1964. 1s. 3d.) also gives information about the available courses of training, their cost, and their location, with the addresses to which application must be made. The booklets can be obtained from H.M.S.O. or from booksellers and their prices vary from 6d. to 2s. 6d.

### American Expedition to New Guinea

IN 1959 the American Museum of Natural History sent an expedition to New Guinea consisting of Leonard J. Brass, leader and botanist, and H. M. Van Deusen, mammalogist. Although the sixth expedition to the Island under the Richard Archbold Foundation, it was the first to cover the north-east—that is, the trusteeship territory of New Guinea—and was based on Lae (*Bulletin of the American Museum of Natural History*, 127, Article 4: *Results of the Archbold Expedition*. No. 83; *Summary of the Sixth Archbold Expedition to New Guinea* (1959). By L. J. Brass. Pp. 145–216+plates 2–3. New York:

American Museum of Natural History, 1964. 2.50 dollars). J. D. Collins, owner of a young coffee plantation, joined them, and they were assisted by six regular employees recruited locally, some with experience of preceding expeditions. Although Brass discusses briefly his classification of vegetation types and compares it with that of Robbins, used as part of the land-use investigations begun in 1953 by the Australian Commonwealth Scientific and Industrial Research Organization, the expedition was essentially to make collections of mammals, amphibians, reptiles and insects, and of plants, for deposition in the American Museum of Natural History—consequently enriched by some 55,000 specimens. After a brief general description of the area, illustrated by 23 excellent photographs, Brass mentions previous collecting expeditions and then details the itinerary from March 22 until December 20. Extensive use was made of air reconnaissance, but there is high praise for the 'Land Rover' used to cover the main journeys. Half the report is then taken up by the description of the 14 collecting stations. In view of the intense activity of Australian scientists over the whole of the eastern half of New Guinea, it seems a little unfortunate that there was apparently little liaison, and five years seems a long time to have waited for the summary report.

### Information Bulletin of the Soviet Antarctic Expedition

PROMPTED by Dr. G. de Q. Robin's review of Volumes 1 and 2 of the Elsevier translations of *Information Bulletin of the Soviet Antarctic Expedition* (*Nature*, 204, 110; 1964) and the pending publication of Volume 3 (the three volumes will cover *Bulletins* 1–30), Dr. Waldo E. Smith, executive secretary of the American Geophysical Union, has written to the Editor as follows: "It is possibly of interest to your readers to know that the American Geophysical Union is continuing this series, more or less on a serial basis . . . Nos. 31–42, inclusive, are available on subscription at a price of 36 dollars and will be published under six covers. The first six of these numbers have already been produced in English edition. It is one of our purposes in undertaking this series to get these on a current basis in order that they might be of maximum use to those engaged in Antarctic studies. We anticipate the other six to be available during the next few months, ending perhaps in January or February. We have plans to continue the series at least through No. 52". Further information can be obtained from Dr. Waldo E. Smith, Suite 506, 1145 19th Street, N.W., Washington, D.C. 20036.

### Queen Elizabeth Forest Park

THE Queen Elizabeth Forest Park in Scotland was established by the Forestry Commission to commemorate Her Majesty's Coronation in 1953. The Park lies within easy reach of Edinburgh, Glasgow and much of industrial Scotland, and is on a well-known and much-frequented touring route. It includes Ben Lomond, the Trossachs, and the undulating forests of Loch Ard and Rowardennan, as well as many picturesque tree-lined lochs. Situated in its midst is the village of Aberfoyle which forms a convenient 'centre'. Within the Park are two distinct types of landscape. To the south and east lie the gently undulating valleys and fertile farmlands of the River Forth, while to the north and west lies the rugged scenery so characteristic of the Scottish Highlands. The park thus lies across the division between Highlands and Lowlands and is crossed by the Highland fault marking the geological division between the two. The *Short Guide to the Queen Elizabeth Forest Park* (Pp. 14+4 photographs and map. London: H.M. Stationery Office, 1964. 1s.) describes its topography, history, botany, forestry and animal life, as well as the literature associated with the Forest. Amenities include the David Marshall Lodge which was presented to the nation by the Carnegie United Kingdom Trust in 1961.

### Medical Subject Headings

It has been announced that *Medical Subject Headings*, the cross-reference guide to the *Index Medicus* and the medical subject heading authority list published annually by the National Library of Medicine, is to be significantly revised. The 1965 issues will contain 579 additional indexing terms, making an overall total of 6,380. The new terminology will be concerned with the following categories: anatomy (category A); diseases (category C); chemicals and drugs (category D); and analytical, diagnostic, and therapeutic technology and equipment (category E). These terms reflect the content of 222 journals which were previously not covered by *Index Medicus*. A total of 208 other journals are being deleted from the *Index Medicus* list. The newly indexed journals cover the fields of dentistry, chemistry, psychology, sociology and veterinary medicine. Indexing terms in *Medical Subject Headings* will continue to appear in alphabetical and categorical lists. Although the format will not change, the alphabetical list will be composed for the first time in upper and lower case letters by GRACE —'Graphic Arts Composing Equipment'—a component of the Library's computer system. *Medical Subject Headings* will be published as Part 2 of the January 1965 *Index Medicus*. Yearly subscriptions to *Index Medicus* are available from the Superintendent of Documents, Government Printing Office, Washington, D.C., at 40 dollars (9 dollars additional for foreign posting). Single issues of *Index Medicus* are available at 3.75 dollars and single copies of *Medical Subject Headings* at 2.50 dollars.

### Research on Immunology

ALL scientists are nowadays aware of the rapid growth and increasing range and importance of research related to immunology. World Health Organization Technical Report No. 286 records the views of the members of five international groups convened by the Organization to consider various aspects of this subject (*Research in Immunology*. Pp. 97. Geneva: World Health Organization; London: H.M.S.O., 1964. 5 Sw. francs; 8s. 6d.; 1.75 dollars). The views expressed do not necessarily represent the views of the Organization or its policy. The subject is discussed under the following five headings; immunoprophylaxis and immunotherapy; immunopathology; tissue antigens and transplantation; immunochemistry; a final section entitled "Programme in Immunology", which includes sections on the training of immunologists and recommendations for research.

### Programmed Instruction Book on Semiconductor Devices

A NEW linear programmed instruction book on semiconductor devices has been published by the Mullard Educational Service. It is based on information previously published by the Service as *A Simple Explanation of Semiconductor Devices*. The book treats the subject in a non-mathematical way, emphasis being given to the physical aspects of electron and hole conduction. A supplementary booklet containing coloured diagrams illustrating semiconductor action is contained at the back of the book. This supplement is referred to by the reader as he progresses through the programme. In a programmed instruction book of this kind the subject is broken down into many small numbered units called frames. Each frame requires from the reader a written response which is compared with the model answer given alongside the frame. The reader goes through the programme at the rate which he finds most natural—an advantage of this new system of learning. A short test included at the back of the book should be attempted before and after completing the programme. In this way the reader is able to assess how much he has learnt from the book. Copies of the book (price 3s. 6d. including supplement) are available from the Mullard Educational Service, Mullard House, Torrington Place, London, W.C.1.

### High-speed Photography

Barr and Stroud manufacture two ultra-high-speed cameras, the 'CP5 Framing Camera' and the 'CP6 Streak Camera'. The 'CP5 Framing Camera' uses the Miller system of optics. The image of the event formed by an objective lens is focused on the surface of a rotating mirror. The light reflected from the rotating mirror sweeps across a number of lenses arranged in an arc, which focus the image on the mirror on to a strip of film. Several different optical systems are available for different framing rates and numbers of pictures. One system, for example, enables 117 pictures, 8-mm diameter, to be taken at  $8 \times 10^6$  pictures per second with an exposure time of 0.12  $\mu$ sec per picture. Facilities are available for synchronizing the camera and the event and for terminating the exposure. A camera of this type was used for the work described in *Nature*, 202, 443; 1964. The 'CP6 Streak Camera' consists of an objective lens which focuses the image of the event on a narrow slit, which is focused by a second lens on to an arc of film via a rotating mirror, which sweeps the image of the slit along the film. The maximum writing speed is 22 mm/ $\mu$ sec with a recording time of 27  $\mu$ sec. Using a 0.05 mm slit a time resolution of  $10^{-8}$  sec is possible. The facilities for synchronization and capping are similar to those of the framing camera.

### Announcements

MR. AUSTEN ALBU, M.P., has been appointed as a member of the Medical Research Council. Mr. Albu is a Governor of both the Imperial College of Science and Technology and Battersea College of Technology. He has been chairman of the Parliamentary and Scientific Committee since 1962.

PROF. A. G. WARD, head of the Procter Department of Food and Leather Science in the University of Leeds, has been appointed chairman of the U.K. Food Standards Committee for a period of three years as from January 1 in succession to Mr. M. W. Perrin, who is giving up the appointment because of pressure of work and other commitments.

THE seventh Castner memorial lecture entitled "Some Achievements in Petroleum Chemicals" will be delivered in London by Dr. H. M. Stanley on March 8. Further information can be obtained from the Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

A SYMPOSIUM on "The Formulation of Pesticides", arranged under the auspices of the Pesticides Group and the Colloid and Surface Chemistry Group of the Society of Chemical Industry, will be held at the School of Pharmacy, London, during March 30–31. Further information can be obtained from the Honorary Secretary of the symposium, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

THE nineteenth annual symposium on fundamental cancer research on "Developmental and Metabolic Control Mechanisms and Neoplasia" will be held in the University of Texas during March 4–6. Topics under discussion will include: biosynthesis and control mechanisms; molecular basis of early development; molecular basis of later development and control; comparative studies on control mechanisms in normal and neoplastic tissues. Further information can be obtained from Dr. D. N. Ward, Department of Biochemistry, University of Texas M. D. Anderson Hospital and Tumor Institute, Houston 25, Texas.

ERRATUM. The communication entitled "Iron-deficient Low-temperature Pyrrhotite", which appeared on p. 175 of the October 10, 1964, issue of *Nature*, is by F. J. Sawkins, Dr. A. C. Dunham and Dr. D. M. Hirst, and not F. J. Sawkins, Prof. A. C. Dunham, F.R.S., . . . as stated in the contents page of that issue.

## ADULT EDUCATION IN BRITAIN

IN opening a debate on adult education in the House of Lords on November 24, Lord Greenhill said there was a real increase to-day in the demand for adult education in Britain. There was, in spite of the expansion in publicly provided education, a still greater demand for advanced education, both technical, cultural and non-vocational, which we could not supply. He urged that additional accommodation, particularly in residential colleges, should be made part and parcel of Britain's normal provision of adult education. He was strongly supported by Lord Hill of Luton, who urged that this was one of the great tasks of to-day following the educational policies of the past twenty years. Those who sought adult education, in the sense in which the term was used by Lord Greenhill in opening the debate, must undergo a disciplined study under the guidance of a competent teacher. Television could play a part in providing this disciplined study only if other links could be created between the teacher and the taught. This would not be easy, but it would be worth while trying to take the fullest advantage of an immensely powerful medium of mass communication, without forgetting that the personality and power of the teacher were essential. Baroness Elliot of Harwood suggested that the adult education organizations should approach the question from a more modern point of view than in the past, seeking to introduce some modern ideas into the classes provided. She also suggested that the pamphlet on consumer education, recently issued by the Research Institute for Consumer Affairs, indicated exciting possibilities for the fusion of adult education and consumer education, starting from practical issues and indicating how adult education and consumer education could create the informed, self-respecting and 'concerned' persons whose influence could be so great on the mind of the society in which we lived.

Lord Chorley directed attention to three groups requiring support. First, there were the evening institutes, and the evening schools for technical education which had scarcely received the recognition they deserved; then there were the refresher courses which were becoming increasingly important in the professions and to which the Robbins Report devoted some attention; the third

group was the movement for bringing up to date the adult population, as a whole, in regard to knowledge—with-out it the modern world was incomprehensible and the adult citizen could not play a proper part in society. Besides this there was the general cultural education mentioned by Baroness Elliot, and Lord Chorley also supported Lord Hill's remarks concerning the need for proper teaching. Lord Francis-Williams thought that, contrary to the views of the Pilkington Committee, establishment of a fourth television channel entirely devoted to education would be useful. He thought we should consider more carefully the possible development of local radio and television linked to the universities, particularly the new universities, which might join with the local education authorities and local adult education associations and possibly with some of the existing correspondence colleges for the purpose. Baroness Gaiskell also believed that this idea of a university of the air would be worth exploring and could be more effective if combined with correspondence courses. She hoped that the Government would put adult education high on its list of priorities in education.

Lord Geddes suggested that a less academic view should be taken of some of the features of adult education, that the Albemarle Report should be taken more seriously, and that adult education for the less intellectual part of the population should be linked with some of the social service activities. He suggested that more research should be encouraged into the causes of anti-social behaviour, and that in this connexion we might consider the possibility of non-military national service which would cover, under disciplined procedures, many facets of social service, such as aid to the old, hospital service, service in under-developed countries and agriculture.

Lord Aberdare, replying to the debate for the Government, pointed out that a good deal had already been done for adult education in Britain: grants to adult education had more than doubled in the period from 1954-55 to 1964-65 and the number of full-time posts had increased from 254 to 311; he also directed attention to what had been done in sound broadcasting in the field of adult education.

## MUSEUM OF LONDON BILL

IN moving the second reading of the Museum of London Bill in the House of Lords on November 26, Lord Champion explained that the London Museum originated with the first Lord Harcourt, and was started in 1911 with private funds made available to form a collection of suitable objects. It soon succeeded in creating interest and attracting gifts and loans. King George V gave permission for the Museum to be housed in the State Apartments and other parts of Kensington Palace where the Museum was opened to the public in 1912. Kensington Palace was never intended to be more than a temporary home, and in 1913 Sir William Lever bought the lease of Stafford House and gave it to the Nation for the joint purposes of housing the London Museum and providing a setting for Government hospitality. The Trustees of the London Museum then placed their collections at the disposal of the Government for the term of the lease of Stafford House, and as long afterwards as the collection should continue to be exhibited there or in some other equally suitable building maintained by the Government. The Government accepted these offers, and undertook financial responsibility for maintaining the London Museum, and from that time onwards the Trustees, apart

from some *ex officio* ones, were appointed by the Prime Minister. The Museum was accommodated in Lancaster House, as Stafford House was re-named, from 1913 until the Second World War when most of the collections had to be put into safe storage and Lancaster House began to be used for international conferences. In 1940 the original lease of the building expired and a new forty-two-year lease was taken by the Ministry of Works from the Crown Estate. After the War the Government decided that the building would continue to be required for conferences and official hospitality and that another home would have to be found for the Museum. In 1949 King George VI gave consent for part of Kensington Palace again to be used by the Museum for a term of fifteen years from December 1950, and this term has been extended by Queen Elizabeth for a further five years to 1970.

Guildhall Museum was founded by order of the Court of Common Council in 1826. The first contribution to the collections consisted of Roman and other antiquities found during the excavations of the foundations of the new post office in St. Martins le Grand. The original concept of the Museum was simply that of an adjunct to

the Library where objects could be seen to illustrate books on the Library's shelves. In 1872, when the new Library wing was opened, the Museum was housed in the basement beneath it and opened to the public. It has continued to be closely integrated with the Library, and the Library Committee of the Common Council is directly responsible for its administration. Since 1921 the Museum has been supported financially by the City of London Corporation. All the objects in Guildhall Museum are connected with the City, many of them consisting of archaeological material, including much that has been unearthed in the course of excavations connected with the re-building of the City since 1946. Guildhall Museum has always been closely associated with the scientific examination of sites cleared for re-building, and it has been generally agreed that all objects found during excavation should be given to the Museum. During the past eighteen years the total number of specimens in the Museum has increased by more than fifty per cent. As a result of war and war-damage the Guildhall collection moved about, and eventually the exhibition, containing about 10 per cent of the collection, came to rest in the Royal Exchange; most of the collection was left in store at Guildhall.

Like the London Museum, Guildhall Museum is thus still waiting for adequate accommodation in a permanent home. Both are essentially local museums, although the London Museum obviously has a far more than local interest. From this situation arose the idea that the accommodation problem might be solved by bringing the

two Museums together under one roof with the cost shared between the Treasury and the County Council and the City of London. The essence of the scheme is that the two Museums will be amalgamated to form a new Museum of London, housed in a new building to be erected for the purpose on a site in the City of London. The capital and running costs will be borne jointly and equally by the Exchequer, the City Corporation and the Greater London Council, which has agreed to accept the obligations entered into by the London County Council in respect of the project. The Museum will be managed by a board of eighteen governors, six being nominated by each of the three authorities. An Interim Board of Governors was constituted on these lines in May 1962, and a Director and Deputy-director-designate were appointed and a firm of architects was invited to prepare a preliminary scheme and estimates. This scheme provides for the Museum building to be on six floors, arranged around a garden court, with its east side forming the base for a 200-ft. high office tower block which will be leased separately by the City Corporation and will be so arranged that some 19,000 sq. ft. of space can be made available for expansion of the Museum at a future date. The Bill provides for payment by the Treasury of a sum not exceeding £150,000 in respect to furniture and equipment, and for the staff of the Museum to be brought within the Corporation's superannuation scheme. Staff salaries will be determined by the Corporation after consultation with the Treasury and the Greater London Council.

## THE BATTELLE INSTITUTE, GENEVA

**I**NDEPENDENT consultative and sponsored research in industry has long been established practice in the United States, perhaps more often than not on a commercial rather than a strictly professional scale, as has been the general tendency over the years in Britain, although to this latter traditional precept there are to-day some noteworthy exceptions successfully established in Britain.

The original aim of the founder of 'Battelle', Gordon Battelle (Battelle Memorial Institute, Columbus, Ohio), was "... to contribute to industrial development by disseminating and using scientific knowledge for purposes of discovery and invention, thereby furthering technical progress". Battelle now has three research centres, at Columbus, Frankfurt and Geneva, with six branch offices in Washington, Los Angeles, Paris, London, Madrid and Gothenburg. It has thus established active and regular relations with industrial and scientific centres, as well as Government authorities throughout the western world; its activities are spreading to some of the so-called developing countries.

A booklet entitled *Ten Years' Research at the Battelle Institute, Geneva\**, has recently been published, marking the completion of ten years' work of this organization in Geneva; it presents a well-documented and illustrated picture of some of the many and varied activities of the

Institute at this particular centre. It is described as "... an invitation to European industry to visit the Institute". The impact of this well-designed and profusely illustrated publication can scarcely fail to impress the reader with the scale on which the Institute operates not only at Geneva but also internationally. A selection of some of the important disciplines covered by this centre includes: economics; applied mathematics; semi-conductors (solid-state physics); electronic paramagnetic resonance; optics; ultra high-vacua; metallurgy and physical properties of materials; refractory ceramic materials; electrochemistry; physical processes of measurement and analysis; electrical engineering and electronics; mechanical engineering; industrial high polymers and petrochemistry; foodstuffs; pharmaceutical and phytopharmaceutical products; chemical engineering; and mathematics and theoretical physics. In connexion with some of these subjects there have resulted "... a total of 252 inventions" in the past few years at Geneva, "... and 1,266 patent applications have been filed in different countries; 587 patents have so far been issued, 221 of them in countries where prior patentability studies are carried out".

The booklet includes 192 references to publications with which the work and staff of the Institute have been concerned in the course of the research projects referred to here. For obvious reasons much sponsored research is of necessity highly confidential as between client and the Institute: to this extent the full story of achievements of the Institute cannot be divulged.

\* *Ten Years' Research at the Battelle Institute, Geneva*. Pp. 71. (Geneva: Battelle Institute, 1964.) Copies are also obtainable from the Battelle Institute, Ltd., 15 Hanover Square, London, W.1.

## COSMOLOGY IN THE U.S.S.R.

**T**HIS account summarizes articles which have appeared in *Priroda*. A. G. Nikolaev and P. R. Popovich (1, 1; 1963) provide photographs of the Earth's surface as seen from a sputnik. G. A. Skuridin (1, 3; 1963)

discusses cosmic physics—the radiation belt of the Earth, interplanetary plasma, primary cosmic radiation, magnetic fields of the Earth and the Moon and short-wave solar radiation. V. V. Shuleikin (4, 53; 1964) gives an account

of experiments on a weightless fluid as observed in a cosmic ship and in a falling vessel. V. V. Kozlov and E. D. Suludi-Kondratiev (6, 44; 1964) discuss lunar geology and tectonics, and they suggest the name "lunite" as a name for the lunar prevalent pumiceous rock, which probably contains 60–65 per cent of silica. K. A. Kulikov (6, 51; 1964) also discusses the problems of the Moon. D. A. Frank-Kamenetsky (11, 17; 1963) suggests that the origin of elements in the solar system is best explained by a hypothesis already proposed by him, namely by their synthesis in a 'cold' gaseous plasma. Ya. B. Zel'dovich (6, 25; 1964) also applied the 'cold' process to the evolution of the pre-star matter consisting of pure hydrogen. N. A. Vlasov (9, 20; 1964) discusses antimatter in the cosmos, while the formation and evolution of organic matter in the cosmos are discussed by A. I. Oparin (6, 29; 1964), (2, 18; 1963) and D. M. Troshin (12, 89; 1963), life on Mars by V. G. Fesenkov (2, 22; 1963), and a review of recent books dealing with life in the cosmos is given by an anonymous reviewer (12, 80; 1963). A description of a newly constructed astrophysical laboratory at Pulkovo, near Leningrad, is given by L. A. Mitrofanova (8, 44; 1964).

I. S. Astapovich (7, 121; 1964) reviews a book on the Tunguska meteorite edited by G. F. Plekhanov and published by Tomsk State University in 1963, being a report on the 1959–60 expedition. The area of fallen trees measures about 2,000 km<sup>2</sup> with thermal effects in its centre. Meteorite fragments were not found. It is suggested that the meteorite did not fall on the Earth but passed through the atmosphere along a parabolic

trajectory. On the other hand Ya. Ya. Yakovlev (9, 113; 1964) describes minute globules of magnetic matter found in the soil in this region. He suggests that the Tunguska meteorite was really due to the explosion of the nucleus of a comet passing through the atmosphere. I. S. Astapovich (10, 87; 1963) reports that on July 12, 1948, a bolide was observed in south-western Turkmenia and that later fragments of iron were collected in the Karakorum desert, suggesting that the bolide was a manifestation of a iron meteorite or a meteoric shower. I. A. Yudin (3, 58; 1964) also reports that in the spring of 1961 a bolide was observed in the Kurgan district and that in July 1963 an iron-bearing olivine-pyroxene chondrite weighing 21.8 kg was found in Kargopolie of Kurgan district. This meteorite was named "Kargopolie". I. S. Astapovich (5, 84; 1964) provides a short review of the alleged falls and problems of ice meteorites. B. I. Vronsky and K. P. Florensky (3, 90; 1964) provide a review of recent work done in the estimation of the quantity of cosmic dust falling on the Earth. A. A. Yavnel (8, 112; 1964) presents a report of the eleventh Meteorite Conference held in Moscow during May 26–30, 1964, when, among other subjects, the origins of chondrites and carbonaceous chondrites were discussed. It was also suggested that the so-called Tunguska meteorite was really due to an exploded comet. K. Tucek (9, 19; 1964) presents a short report on a conference on 'Tectites' held in Czechoslovakia during June 6–7, 1964, mainly to study local tectites, formerly called moldavites and now called vltavites, after the river Vltava, which the Germans called Moldau.

## MAGNETIC EVIDENCE FOR TRINUCLEAR CLUSTERS IN RHENIUM(IV) CHLORIDE

By DR. R. COLTON and PROF. R. L. MARTIN

Department of Inorganic Chemistry, University of Melbourne

**R**HENIUM(IV), with an electronic configuration  $5d^3$ , usually shows a magnetic moment corresponding to three unpaired electrons in its octahedral halocomplexes of the type  $M_2ReX_6$  (ref. 1). In contrast, the magnetic moment of rhenium(IV) chloride appears to be anomalously low<sup>2</sup>, suggesting the presence of some unusual structural feature.

Recent determinations of the crystal structures of caesium tetrachlororhenate(III)<sup>3–5</sup>, rhenium(III) chloride<sup>6</sup> and certain other halocomplexes of rhenium(III)<sup>7</sup> have revealed that in all these compounds the basic structural unit consists of three rhenium atoms in a triangle with one halogen atom bridging each pair of rhenium atoms. The remaining halogens are arranged approximately at the corners of an octahedron around each rhenium atom.

It seems likely that such clusters may also occur in oxidation states other than rhenium(III) and indeed with other elements. Accordingly, we have re-examined the recently reported magnetic properties of rhenium(IV) chloride and find that they can, in fact, be nicely accommodated on the basis that the compound contains trimeric units,  $Re_3Cl_{12}$ .

The bonding and magnetism of rhenium(IV) chloride are tractable in terms of a molecular orbital (M.O.) description. We follow here an L.C.A.O.-M.O. treatment in the Hückel approximation of the type foreshadowed by Bertrand, Cotton and Dollase<sup>4</sup> to describe the bonding in the diamagnetic  $[Re_3Cl_{12}]^{3-}$  anion. We assume that the  $Re_3Cl_{12}$  molecule belongs to the point group  $D_{3h}$  and that the immediate environment of each rhenium atom is comprised of five chlorine atoms arranged at the corners of a slightly distorted octahedron (Fig. 1). The sixth lobe of

an octahedral  $5d^26s6p^3$  hybrid  $\sigma$ -set centred on each rhenium is then naturally orientated towards the centre of the  $Re_3$  triangular core, three such lobes forming a basis for M.O.s with the irreducible representations  $a_1'$  (bonding) and  $e'$  (anti-bonding) in the point group  $D_{3h}$ . Likewise, the residual set of  $5d$  orbitals of each rhenium atom forms a basis for M.O.s which can be classified in  $D_{3h}$  into the species  $a_1''(d_{yz})$ ,  $e'(d_{xy})$  and  $e''(d_{xz})$  (bonding) and  $a_1'(d_{zz})$ ,  $e''(d_{yz})$  and  $a_2'(d_{xy})$  (antibonding). It is sufficient for the present purposes to estimate qualitatively the magnitude of the splittings from the directional properties of the  $5d$  orbitals using the assumption that the splittings between a given bonding orbital and its antibonding counterpart are roughly proportional to the

Fig. 1. Structure proposed for  $Re_3Cl_{12}$ .

Fig. 2. Highest molecular orbitals for  $\text{Re}_3$  core of: (a)  $\text{Re}_3\text{Cl}_3$  and  $\text{Re}_3\text{Cl}_{12}^{3-}$ ; (b)  $\text{Re}_3\text{Cl}_{12}$ ; (c)  $\text{Re}_3\text{Cl}_{12}^{3+}$ . Not drawn to scale. Point group symmetry  $D_{3h}$ .

overlap integral. The bonding scheme which emerges for the  $\text{Re}_3$  core of the 'united' trimer is given in Fig. 2. For rhenium(IV) chloride, a ground state electronic configuration  $(a_1')^2 (a_2'')^2 (e')^4 (e'')^1$  should be associated with a single unpaired electron per trimer with a consequential magnetic moment of 1.0 B.M. per Re atom. Like  $\text{Re}_3\text{Cl}_3$  and  $\text{Re}_3\text{Cl}_{12}^{3-}$ , Re-Re metal-to-metal bonds cement the  $\text{Re}_3$  core in  $\text{Re}_3\text{Cl}_{12}$  into a structurally stable unit.

The variation with temperature of the magnetic susceptibility of rhenium(IV) chloride is given in Table 1. Extrapolation to infinite temperature of a plot of molar susceptibility against reciprocal absolute temperature shows the presence of a substantial temperature independent contribution to the paramagnetism of about  $230 \times 10^{-6}$ . A re-evaluation of the experimental data with the inclusion of this term reveals that the magnetic moment of rhenium(IV) chloride is 1 B.M. and virtually independent of temperature as required for the trimer model.

Table 1. MAGNETIC PROPERTIES OF RHENIUM(IV) CHLORIDE

Temp ( $^{\circ}\text{K}$ )	$\chi_M \times 10^6$	$\mu(\text{B.M.}) = 2.84[(\chi_M - 230) \times 10^{-6} T]^{1/2}$
304	654	1.02
275	695	1.02
255	730	1.01
240	766	1.02
215	807	1.00
189	888	1.00
158	1,016	1.00
143	1,132	1.02
123	1,311	1.03
114	1,418	1.04
96	1,693	1.06
92	1,840	1.09
87	2,054	1.13

Only one method of preparation of rhenium(IV) chloride has so far been reported, namely, the action of thionyl chloride on hydrated rhenium dioxide<sup>8</sup>. Unfortunately, when prepared in this way the material is amorphous and the highly desirable X-ray diffraction patterns cannot be obtained. However, strong corroborative evidence for the existence of metal-to-metal interaction in rhenium(IV) chloride is available both from its chemical properties and the magnetic properties of some of its simple derivatives. For example, when rhenium(IV) chloride is dissolved in aqueous alkali, a red-brown solution is obtained which possesses the same remarkable inertness to chemical attack as that exhibited by acidic solutions of rhenium(III) chloride. Furthermore, although exactly one-quarter of the total chlorine content of  $\text{ReCl}_4$  can readily be precipitated as silver chloride, the remaining chlorine can be

extracted only by fusion with alkali<sup>8</sup>. Such facts are consistent with a single labile chlorine atom attached to each rhenium atom of an extremely stable  $\text{Re}_3\text{Cl}_3$  core. The X-ray examinations of the rhenium(III) compounds noted earlier have revealed that each in-plane terminal Re-Cl band is abnormally long and chemically reactive<sup>3-7</sup>. It is also relevant that the monomeric phosphine derivative of rhenium(IV) chloride,  $\text{ReCl}_4(\text{PET}_3\text{Ph})_2$ , synthesized by indirect methods<sup>9</sup>, has a magnetic moment of 3.64 B.M. ( $20^{\circ}\text{C}$ ), which is normal for the  $d^3$  configuration of octahedral rhenium(IV).

An interesting feature which emerges from our simple L.C.A.O.-M.O. treatment is the prediction that a trinuclear rhenium(V) cation  $[\text{Re}_3\text{Cl}_{12}]^{3+}$  may exist which could be of comparable stability to the trimer structures already known.

The magnetic properties of this cation would decide which of the  $e'(d_{xy})$  and  $a_2''(d_{yz})$  bonding M.O.s lies lower since the alternative ground configurations  $(a_1')^2 (e')^4$  and  $(a_1')^2 (a_2'')^2 (e')^2$  are diamagnetic and paramagnetic, respectively. This question cannot be unambiguously resolved in the present approximation and we are therefore attempting to prepare and isolate such a species.

Finally we note that a valence bond description of the type originally proposed<sup>3</sup> for the  $[\text{Re}_3\text{Cl}_{12}]^{3-}$  anion in terms of a spin-paired  $5d^3 6s 6p^3$  hybrid  $\sigma$ -set for each rhenium atom is somewhat less satisfying for rhenium(IV) chloride. Thus the spin-paired configuration  $d^3$  leads to 1 rather than  $1/3$  of an unpaired electron per rhenium atom, although the latter result could be accommodated by the introduction of additional spin-spin coupling.

We thank Drs. C. G. Barraclough and R. D. Harcourt for their advice.

*Note added in proof.* Since this communication was submitted for publication, extensive chemical, spectrophotometric and X-ray structural investigations by F. A. Cotton's group<sup>10-14</sup> in the U.S.A. and J. E. Fergusson's group<sup>15</sup> in New Zealand have confirmed the pronounced tendency of  $\text{Re(III)}$  to form trimeric clusters. In our discussion here of the magnetic evidence for trimeric rhenium(IV) species, we inadvertently overlooked that the L.C.A.O.-M.O. treatment of the  $[\text{Re}_3\text{Cl}_{12}]^{3-}$  anion foreshadowed in reference 4 had in fact appeared in reference 13. The two treatments happily lead to the same order of energies for the bonding molecular orbitals of the  $\text{Re}_3$ -core (the respective reference sets of co-ordinate axes are rotated so that the present  $x = x, y = z$  and  $z = y$ ), but the more elaborate analysis of Cotton and Haas suggests a somewhat different order of energies for the antibonding species. These differences are of no consequence in the present discussion of the bonding and magnetism of rhenium(IV) chlorides.

# AN EFFECT OF ETHAMBUTOL, 2,2'(ETHYLENEDIIMINO)-DI-1-BUTANOL-, ON THE STRUCTURE AND ACTIVITY OF ALCOHOL DEHYDROGENASE

By EDWIN A. PEETS

Department of Pharmacological Research, Lederle Laboratories Division, American Cyanamid Co., Pearl River, New York

THE observation that the regulation of enzymatic reactions by certain substances is accompanied by changes in the molecular configuration of the enzyme has been reported by several investigators<sup>1-4</sup>. In recent investigations in these laboratories on dextrorotatory 2,2'(ethylenediimino)di-1-butanol-, ethambutol, a new antituberculosis drug<sup>5</sup>, it was observed that the drug could serve as a substrate for alcohol dehydrogenase<sup>6</sup>, and moreover that the compound served to stimulate ethanol oxidation by the enzyme. This article presents the results of the preliminary investigations of the stimulation of alcohol dehydrogenase by ethambutol, and evidence is presented which indicates that stimulation of the enzyme is accompanied by alterations in its molecular configuration.

Yeast alcohol dehydrogenase used in this experiment was obtained from the Mann Research Laboratories as crystals or as a crystalline suspension, and was dissolved in 0.05 M phosphate buffer, pH 8.0, prior to use. Ethambutol and its *l* isomer were prepared in these laboratories.

The assay system for alcohol dehydrogenase contained 3  $\mu$ moles DPN, 218  $\mu$ moles of ethanol, and from 2 to 8 units of alcohol dehydrogenase in a total volume of 30 ml. of pH 8.0, 0.05 M phosphate buffer. In some experiments the enzyme was pre-incubated in 1.0 ml. of buffer containing 72  $\mu$ moles of either ethambutol, its *l* isomer, or EDTA, for up to 120 h at 4° C, and 0.1 ml. of this enzyme solution was used in the assay; control enzyme was pre-incubated in the buffer under similar conditions without the test compounds. When the enzyme was not pre-incubated, 5.8  $\mu$ moles of ethambutol or its *l* isomer were added at the time of assay, and the assay systems of the pre-incubated enzyme contained 7.2  $\mu$ moles of the drug. Alcohol dehydrogenase activity was assayed spectrophotometrically by following increase in absorbance at 340 m $\mu$  in the Cary recording spectrophotometer at 25° C.

Gel filtration and sedimentation analysis were performed on control and drug-treated enzyme after incubation for

Fig. 2. Elution diagram of alcohol dehydrogenase from 'Sephadex G-200' in the presence of ethambutol. Control refers to enzyme in buffer alone. —, control; ---, ADH + ethambutol

24 h as described here. The gel filtration was performed on a 2 cm x 28 cm column of 'Sephadex G-200' gel at 4° C. The enzyme was eluted from the column with pH 8.0 phosphate buffer at a flow rate of about 2 ml./h, and 4-ml. fractions were collected for assay. Protein concentrations in the fractions were determined by measuring the absorption at 280 m $\mu$  in the Beckman spectrophotometer. Sedimentation experiments were performed in the Spinco model E analytical ultracentrifuge at a speed of 52,640 r.p.m. at 20° C.

The alcohol dehydrogenase catalysed oxidation of ethanol by DPN was stimulated by incubation of the enzyme with ethambutol or by addition of the drug to the control enzyme at the time of assay (Fig. 1). When the enzyme was incubated with ethambutol the extent of stimulation varied from 1.4 to 3.7 times that of the control rate depending on the time of incubation. Similar incubations of the enzyme with the *l* isomer or additions of the *l* isomer to the control enzyme resulted in stimulation of activity 1.6-1.7 times that of the control. Incubation of the enzyme with an equimolar concentration of EDTA did not stimulate ethanol oxidation, and instead depressed its activity slightly (Table 1).

No measurable production of DPNH could be observed with the amount of enzyme used in these experiments when it was presented with ethambutol or its *l* isomer as a substrate in the absence of ethanol (Fig. 1). Assay of the activity of enzyme incubated with ethambutol for 7 days and then dialysed against pH 8.0 phosphate buffer for 20 h at 4° C indicated that the stimulation of enzyme activity persisted. Although all the ethambutol was not removed, there was an indication that the continued presence of the drug at its initial concentration was not required for enhanced activity once the enzyme had been exposed to ethambutol (Fig. 1d).

Fig. 1. Effect of ethambutol on alcohol dehydrogenase catalysed oxidation of ethanol. A, enzyme, pre-incubated with ethambutol; B, control enzyme; C, control enzyme to which drug had been added at the time of assay

Table 1. RATIO OF ACTIVITY\* OF DRUG-TREATED ALCOHOL DEHYDROGENASE TO CONTROL ENZYME

Time (h)	Pre-incubated enzyme		
	Ethambutol	<i>l</i> Isomer	EDTA
1		1.7	
1	1.4	1.7	0.74
3		1.6	
4	1.9		
24	3.7	1.7	0.88
120	1.9		

\* Activity is calculated as:  $\frac{[\Delta A_{340}/30 \text{ sec}] \times 2}{\mu\text{g enzyme}}$

In the absence of ethambutol, alcohol dehydrogenase was eluted from a gel column as a single peak trailed by a small amount of some component of lower molecular weight, estimated to be 8 per cent of the total enzyme. On the other hand, when ethambutol was present the elution pattern demonstrated that there was an increase in the amount of the secondary component which amounted to 22 per cent of the total enzyme (Fig. 2). Accompanying this increase in the amount of the secondary enzyme fraction was a concurrent decrease in that of the main component. The suggestion of a slight increase in elution volume of the enzyme from the column in the presence of ethambutol further indicated a change of the physical characteristics of the enzyme.

The results of the gel-filtration experiments indicated that in the presence of ethambutol there was an alteration of the molecular size of the enzyme since in principle the gel is able to distinguish between structures of different molecular weight. This change in the state of the enzyme could best be described as a depolymerization of a normally aggregated molecule into a disaggregated state.

The effects of ethambutol on the gross state of aggregation of the alcohol dehydrogenase molecule were further demonstrated by the sedimentation experiments. It was apparent that the enzyme consisted of aggregated and disaggregated components (Fig. 3A) sedimenting at faster and slower rates respectively, and that ethambutol caused a further disaggregation of the enzyme into its slower sedimenting sub-unit (Fig. 3B). The proportion of the enzyme sub-unit increased from 25 per cent of the total material in the untreated enzyme to 56 per cent when alcohol dehydrogenase was treated with ethambutol. The increase in the amount of the sub-unit was accompanied by a decrease in that of the aggregated enzyme. The sedimentation coefficient of the sub-unit of the enzyme in both the untreated and the drug-treated enzyme was calculated as 2.8 S (this value uncorrected for viscosity and concentration).

These experiments indicated that activation of alcohol dehydrogenase of yeast by ethambutol (or its *l* isomer)

Fig. 3. Effect of ethambutol on sedimentation behaviour of alcohol dehydrogenase. A, control enzyme; B, enzyme treated with ethambutol. Sedimentation is from right to left.

was associated with changes in the state of aggregation of the sub-units of the enzyme. The stimulatory effect of the *l* isomer indicated that there was no stereochemical requirement for the action of the drug, and from the lack of stimulatory activity of EDTA it was concluded that chelation *per se* was not likely to be the primary mechanism in the dissociation of the enzyme. While the exact mechanism of stimulation could not be established, the possibility exists that the disaggregated form of the enzyme produced by ethambutol was much more active than the aggregated form.

I thank Drs. D. A. Buyske and J. R. Florini for their advice and M. C. Davies for performing the centrifugation analyses.

## CHOLINESTERASE-CONTAINING PATHWAYS OF THE HINDBRAIN: AFFERENT CEREBELLAR AND CENTRIFUGAL COCHLEAR FIBRES

By DR. C. C. D. SHUTE and DR. P. R. LEWIS

Department of Anatomy, University of Cambridge

IN a recent investigation<sup>1</sup> we showed that an extensive neuronal system, probably corresponding to the ascending reticular activating system, could be demonstrated in the rat forebrain by a combined surgical and histochemical technique for cholinesterases. We have since, in collaboration with Dr. Ann Silver<sup>2</sup>, compared the acetylcholinesterase and choline acetylase content of fibres supplying the hippocampal formation, and the changes which occur after lesions of the fornix. The correspondence was such as to prove beyond reasonable doubt that the cholinesterase-containing fibres which travel in the fornix and terminate on the hippocampus

and dentate gyrus are cholinergic. We conclude, therefore, that our method is likely to be valid for cholinergic pathways in the central nervous system generally, and we have now extended it in the rat to cover the hindbrain.

Stereotaxic lesions, produced by radio frequency current, were placed in selected regions of the medulla, cerebellum and cerebellar peduncles. Most of the animals were killed after four days, which we have found to be the optimum time in the forebrain for enzymatic pile-up. Some were allowed to survive longer in order to demonstrate enzymatic loss. After sectioning, the brains were treated by the thiocholine technique. The response to

Fig. 3

Fig. 3. Pile-up of acetylcholinesterase in fibres of the inferior cerebellar peduncle

injury shown by cholinesterase-containing fibres was essentially similar to that observed in the forebrain. Thus, where the intra-medullary fibres of the facial nerve were involved by a lesion dorsomedial to the motor facial nucleus, acetylcholinesterase piled up in the interrupted axons on the cell body side. In another experiment involving the acetylcholinesterase-containing bundle which we have shown to consist of olivo-cochlear and salivatory fibres<sup>3</sup>, enzyme was lost from the cut ends of axons on the side remote from their cells of origin. We found that the proximal part of the olivo-cochlear pathway could be followed, through the superior olivary peduncle, back to its origin (from retro-olivary and pre-olivary reticular cells) in sections cut from normal fresh brain and fixed briefly in formalin before histochemical treatment (Fig. 1).

We investigated the course of reticular fibres by placing large lesions in the dorsomedial and ventromedial regions of the reticular formation of the medulla. In each case acetylcholinesterase was found to pile up in severed reticular axons, but only on the caudal side of the lesion. We have never found evidence of descending reticular pathways containing cholinesterase in the brain stem. We consider, therefore, that only ascending reticular fibres are cholinergic, and that descending reticulo-spinal pathways operate through some transmitter other than acetylcholine, possibly a mono-amine<sup>4,5</sup>.

Lesions involving any of the cerebellar peduncles invariably produced pile-up of acetylcholinesterase on the side remote from the cerebellum, and the response in the middle peduncle was no less extensive than that which occurred when either of the other peduncles was damaged (Figs. 2 and 3). We conclude from these findings that a significant influx of cholinergic afferents reaches the cerebellum by all three peduncles, and not mainly by the superior and inferior peduncles as has been suggested<sup>6</sup>. The cholinesterase-containing afferents in the middle peduncle, in spite of their fine calibre, can be recognized in normal material. Those of the superior and inferior peduncles become more apparent after the fibres have been interrupted, probably because they are scattered among the numerically preponderant non-cholinergic fibres.

In addition to the peduncular pathways, we have found a fourth route by which cholinergic fibres may reach the cerebellum, namely, the dorsal longitudinal fasciculus of Schütz. Cholinesterase-containing fibres in this fasciculus ascend on either side of the mid-line in the floor of the fourth ventricle, then swing outwards to enter the cerebellum on the inner side of the superior peduncle. Interruption of the dorsal longitudinal fasciculus resulted in a loss of staining in the ventricular floor above the lesion, and also round the cells of the nucleus coeruleus which is interpenetrated by these fibres (Fig. 4). The dorsal longitudinal fasciculus has usually been regarded in the past as a purely descending pathway.

The origin of the cholinesterase-containing afferents to the cerebellum was investigated mainly in unoperated material. The fibres which travel in the middle peduncle arise in part at least from the nucleus reticularis tegmenti pontis. Some of the fibres of the superior peduncle appear to have a midbrain origin from the laterodorsal tegmental nucleus, and traverse the portion of the peduncle occupied by the unstained dentato-rubral fibres. Other, finer fibres

Fig. 4

Fig. 5. Acetylcholinesterase-containing bipolar cells in the white matter of the flocculus

of the superior peduncle ascend with the unstained fibres of the ventral spino-cerebellar tract. The fibres of the inferior peduncle arise from cholinesterase-containing cells of reticular type situated among the cells of the lateral cuneate nucleus, and from similar cells in the spinal trigeminal nucleus and the cuneate and gracile nuclei. The dorsal longitudinal fasciculus conveys fibres from the nucleus eminentiae teretis, from the gracile nucleus, and from the paramedian reticular nucleus; they are joined by fibres from the nucleus coeruleus. We are thus able to confirm the earlier claim<sup>7</sup>, afterwards denied by various workers<sup>8</sup>, that the gracile and cuneate nuclei send projections to the cerebellum.

Experimental as well as normal material was used to determine the course and distribution of cholinesterase-containing fibres within the cerebellum. With the exception of the flocculus and paraflocculus, the lateral portions of the cerebellum were found to be much less richly innervated than the vermis. Many of the fibres derived from the superior peduncle were shown to decussate within the cerebellum. When a lesion was placed in the cerebellar white matter so as to interrupt these fibres, enzyme piled up on the medial side in fibres that had already crossed, as well as on the lateral side in uncrossed fibres. Other cholinesterase-containing fibres associated with the superior peduncle can be seen to cross in the superior medullary velum. Fibres from the middle peduncle supply preferentially the paraflocculus and the declival portion of the lobulus simplex (sub-lobules VIb and VIc of Larsell<sup>9</sup>). Some earlier investigations in the cat<sup>10,11</sup> suggest that the declive may be concerned with the functional organization of the head and neck. The role of the paraflocculus is uncertain, but it may regulate the activity of axial musculature<sup>12</sup>.

In addition to the paraflocculo-declival tract, there is another distinct bundle of cholinesterase-containing fibres to be seen within the cerebellum, which we have called the cochleo-flocculo-nodular tract. Its fibres run caudally from the region of the superior vestibular nucleus and are distributed to the cochlear nuclei and to the flocculo-nodular lobe. In an experimental animal in which the tract was partly divided, enzyme was found to pile up in the ends of damaged fibres rostral to the lesion and to be lost on the caudal side from terminals in the dorsal cochlear nucleus. Another animal, in which the floccular stalk was severed at its base, showed some evidence of enzyme loss in the fibres supplying the flocculus. There are, however, many cholinesterase-containing cells within the white matter of the flocculus which are not affected by severing its stalk. These cells tend to be fusiform and are apparently bipolar (Fig. 5): they resemble cells which we have found grouped on the course of cholinergic bundles in the forebrain, for example, in the nucleus of the ventral supraoptic decussation.

The cholinesterase-containing afferents to the rat cerebellum appear to terminate mainly within the granular layer of the cortex, although in some other genera many such fibres may reach the molecular layer<sup>13</sup>. They probably contribute to the glomeruli formed by the terminals of mossy fibres synapsing with the dendrites of the granule cells. The glomeruli, however, are not responsible for all the cholinesterase of the granular layer as has been stated<sup>14</sup>, nor is all the enzyme derived from afferent terminals, since acetylcholinesterase is also found in the bodies of Golgi cells<sup>15</sup>. These interneurons are somewhat larger than the granule cells, and have short axons which project on to the glomeruli. They are scattered throughout the granular cortex, but are much more prevalent in the flocculo-nodular lobe and in the roof of the postero-lateral fissure between the flocculo-nodular lobe and the uvulo-paraflocculus<sup>16</sup>, that is, in the regions of the cortex which receive vestibulo-cerebellar fibres. The acetylcholinesterase content of the Golgi cells is largely responsible for the greater concentration of this enzyme which characterizes the vestibular portion of the

Fig. 6. Sagittal 100- $\mu$  section through the cerebellum showing concentration of Golgi cells in the vestibular receiving areas of the vermis. L, lingula; N, nodule; U, uvula.

cerebellum (Fig. 6). The lingula does not contain significantly more Golgi cells than other areas of vermal cortex, except in the region immediately adjacent to the nodule, which may receive an overspill of vestibular fibres. In animals where lesions had been placed in the cerebellar white matter, the Golgi cells of the overlying denervated cortex did not lose their enzyme.

Other cells which contain acetylcholinesterase are those of the dentate (Fig. 2) and other cerebellar nuclei. Here the enzyme is present in relatively small amounts, and in the rat there is not the preponderance of pseudo-cholinesterase which has been reported in the horse<sup>17</sup>. Unlike their cells of origin, the fibres of the dentato-rubral tract which comprise the greater part of the superior peduncle are quite devoid of cholinesterase. In view of this, and of the observation that the cerebellar nuclei contain less choline acetylase than does the superior peduncle<sup>18</sup>, we conclude that the dentate neurones and those of the other cerebellar nuclei are non-cholinergic, and that the cholinesterase, which is contained in their cell bodies and dendrites without extending into the axons, is postsynaptic.

Acetylcholinesterase is also found in small quantities elsewhere in the brain stem in the cell bodies of neurones which are not likely to be cholinergic, for example, in the trapezoid nuclei and in the mesencephalic trigeminal nucleus (Fig. 4). In general, therefore, one may say that the presence of acetylcholinesterase in the cell body of a neurone cannot be regarded as an indication that it is cholinergic unless the enzyme is also present in the axon and in the presynaptic terminals. In the case of neurones with short axons this may be difficult to determine, and in consequence it is by no means certain that the cerebellar Golgi cells are cholinergic. In view of the relatively low choline acetylase content of the cerebellar cortex<sup>18,19</sup>, it seems most likely that they are not. The presence of acetylcholinesterase may, however, indicate that they are cholinceptive.

In spite of the report that in cats the Purkinje cells are excited by cholinergic drugs while the granule cells are not<sup>20</sup>, the distribution of enzyme suggests that, in the rat at least, the main cholinceptive cells of the cerebellar cortex apart from Golgi cells are likely to be the granule cells through the glomeruli. In view of the absence of cholinesterase in their cell cytoplasm and the low cortical choline acetylase levels, the granule cells can scarcely be cholinergic. Where they have been interpreted as such<sup>15</sup>, the cholinesterase-containing fibres of the cerebellar white matter have been missed, and consequently the cholinesterase-containing axons of the granular cortex have wrongly been regarded as belonging to the granule cells. The apparent localization of acetylcholinesterase in the nuclei of granule cells, described by other workers<sup>20</sup>, we take to be a histochemical artefact.

Fig. 7. Exploded diagram of hindbrain, showing the presumed cholinergic innervation of the cerebellum and cochlear nuclei. *B*, superior vestibular nucleus; *BU*, superior cerebellar peduncle; *BP*, middle cerebellar peduncle; *D*, dentate nucleus; *DC*, dorsal cochlear nucleus; *DE*, declive of lobulus simplex; *F*, flocculus; *FA*, fastigial nucleus; *I*, nucleus interpositus; *L*, lingula; *N*, nodule; *P*, fissura prima; *PF*, parafocculus; *RB*, inferior cerebellar peduncle; *RP*, nucleus reticularis tegmenti pontis; *V*, trigeminal nerve; *Vm*, motor trigeminal nucleus; *VC*, ventral cochlear nucleus; *VII*, facial nerve; *VIIIm*, facial nucleus; *VIIIc*, cochlear nerve; *VIIIe*, vestibular nerve.

We have made use of the data obtained from our experiments to construct a map of the main cholinesterase-containing pathways of the cerebellum (Fig. 7). This diagram consists of transverse sections of the brain stem taken at 1-mm intervals and set at ten times their natural distance apart. The superior, middle and inferior cerebellar pathways represent the fibres travelling respectively in the superior, middle and inferior cerebellar peduncles, and the dorsal longitudinal pathway represents the fibres of the dorsal longitudinal fasciculus. We believe that these pathways, as illustrated, constitute a cholinergic reticular activating system supplying the cerebellum and cochlear nuclei, comparable to the system which we have described as innervating cortical and subcortical structures in the forebrain.

Although the anatomical projections of the reticular formation to the cerebellum have been well worked out<sup>12</sup>, more clearly indeed than those to the cerebral hemispheres, much less is known of possible activating effects than in the case of the cerebral cortex. There is evidence that the lateral reticular nucleus which contributes fibres to the inferior cerebellar peduncle is fired by collaterals from spinal<sup>21</sup> and trigeminal<sup>22</sup> tactile pathways. With regard to the role of cholinergic neurones, the balance of evidence favours the view that the physiological effect of released acetylcholine on neuronal activity is likely to be facilitatory, especially in the cerebral cortex<sup>23</sup>. It has been suggested that certain centrally active drugs may produce their depressant or stimulant effects by respectively blocking or augmenting the release of acetylcholine<sup>24</sup>.

The possibility must also be considered that in some circumstances cholinergic neurones may have an inhibitory action, and so produce the filtering effect on sensory input which has been regarded as an essential

function of the reticular formation<sup>25</sup>. Acetylcholine has been shown to depolarize and depress conduction in non-myelinated fibres of the vagus<sup>26</sup>. It also depresses neuromuscular transmission in the frog, and the block is said to be partly presynaptic<sup>27</sup>. Conduction in the auditory nerve is depressed by high-frequency stimulation of the olivo-cochlear bundle<sup>28</sup>, and we have shown that this bundle contains fibres which may be presumed to be cholinergic. There is some reason for supposing, however, that the depression of auditory action potentials caused by olivo-cochlear stimulation may not involve release of acetylcholine, since the effect is not modified by eserine<sup>29</sup>, and occurs optimally under deep pentobarbitone or chloralose anaesthesia: conditions which do not favour cholinergic mechanisms<sup>24,30</sup>.

In an attempt to discover whether all the fibres of the olivo-cochlear bundle contain acetylcholinesterase, we have compared serial sagittal sections of the brain stem stained alternately by the thiocholine method and with silver. It was evident that, while the cholinesterase-containing fibres are aggregated into a compact bundle, there are many fibres devoid of cholinesterase which cross the midline adjacent to this bundle and might possibly be affected in stimulation experiments. Whether such fibres reach the cochlea is not known, although further evidence bearing on the problem may yet emerge from electron microscopy. Certain types of nerve ending have been seen in the organ of Corti which could belong to efferent fibres, and of these some connect with the bases of hair cells, while others end almost exclusively in relation to other nerve endings<sup>31</sup>. It is conceivable that, while the latter are inhibitory, the former are at least partly facilitatory, since stimulation of the olivo-cochlear bundle also results in a small increase in the cochlear microphonic potentials generated by the hair cells. It

would be illuminating to know whether either or both types of ending contain cholinesterase.

This work was supported by a Medical Research Council grant. We thank Miss Annette Pine and Mr. H. Williams for assistance, and Mr. J. F. Crane and Mr. G. Oakes for photography.

## DISK ELECTROPHORESIS OF HUMAN SERUM LIPOPROTEINS

By PROF. K. ANANTH NARAYAN, SUHASINI NARAYAN and PROF. FRED A. KUMMEROW

Burnsides Research Laboratory, University of Illinois, Urbana

SINCE the first successful isolation of a lipoprotein from horse serum by Macheboeuf<sup>1</sup>, considerable attention has been devoted to this class of conjugated proteins<sup>2</sup>. Recently, Barclay *et al.*<sup>3</sup> reported the presence of two new lipoprotein components in the human HDL<sub>2</sub> fraction ( $1.063 < d < 1.125$ ). Analytical ultracentrifugation and moving boundary electrophoresis are very precise tools, but they lack the resolution of the newly developed disk electrophoretic method<sup>4</sup>. For example, normal human serum is generally resolved into 3-5 components by these methods whereas over 20 components have been demonstrated by disk electrophoresis. Zone electrophoresis of serum lipoproteins has been examined by a number of investigators with a variety of media such as starch granules, polyvinyl resin, starch gel and paper<sup>5-7</sup>. However, it is not possible to vary the pore size of these media as readily as in the case of polyacrylamide gel, which is the supporting medium used for standard disk electrophoresis. Acrylamide-gel electrophoresis of lipoproteins has not been previously reported in the literature. In this article,

we would like to report disk electrophoretic experiments of the usual lipoprotein fractions (LDL,  $d < 1.063$ ; HDL<sub>2</sub>,  $1.063 < d < 1.125$ ; HDL<sub>3</sub>,  $1.125 < d < 1.21$ ) and to relate these data to the observed flotation patterns.

One pint of fasting blood was obtained from one of the authors (K. A. N.) and the serum derived from this blood was used for the isolation of lipoprotein fractions 1 (LDL), 3 (HDL<sub>2</sub>) and 5 (HDL<sub>3</sub>) according to the method of Havel *et al.*<sup>8</sup>. All lipoprotein solutions and the salt solutions used for dialysis contained 0.05 per cent versene. The procedure used for disk electrophoresis was a modification of the original disk electrophoretic procedure of Ornstein and Davis, and made use of 20 per cent sucrose mixed with solution B<sup>4</sup> as the anti-convection medium rather than sample gel. Prestaining of lipoprotein fractions or serum was carried out according to the procedure of Ressler *et al.*<sup>7</sup>. Tracking dye was not used, because preliminary experiments indicated that this dye also bound other proteins in addition to albumin and interfered with the visualization of the lipoproteins. Variations in gel concen-

Fig. 1. Disk electrophoretic patterns. (Lipid prestain.) 7.5 per cent gel. LDL (D 99-1), HDL<sub>2</sub> (D 99-3), HDL<sub>3</sub> (D 99-5, 7), 30 $\mu$  each, 2.5 m.amp, 73 min for LDL and HDL<sub>2</sub> and 85 min for HDL<sub>3</sub>.

Fig. 2. Disk electrophoretic patterns. (Lipid prestain.) 3.75 per cent gel. LDL (D 150-1), HDL<sub>2</sub> (D 150-2), HDL<sub>3</sub> (D 150-3), 10 $\mu$  each, 2.5 m.amp, 34 min.

trations were obtained by suitable adjustment of the volume of solution *C* and water in the formula provided by Ornstein and Davis<sup>4</sup>. Analytical ultracentrifugation was performed with a Spinco model *E* ultracentrifuge at 52,640 r.p.m.

When the standard 7½ per cent polyacrylamide was used for the main gel, the prestained lipoprotein fractions resolved as shown in Fig. 1. The pore size of this gel has been estimated to be 50 Å and the large molecules (*LDL*, fibrinogen, 19 *S* γ-globulin) do not penetrate the gel<sup>4</sup>. *LDL* did not enter the main gel as seen in *D* 99-1. *HDL*<sub>2</sub> (*D* 99-3) and *HDL*<sub>3</sub> (*D* 99-5, 7) resolved into only 3 components. When a protein stain such as amido black was used a trace component having the mobility of albumin was also observed in all fractions. In these experiments, the lipoprotein fractions were used as such in their respective salt solutions without prior dialysis. In disk electrophoresis, which is conducted at very low ionic strength, the presence of even small amounts of salt in the sample could reduce the mobility of the protein constituents. The dark stain observed on top of the spacer gel was merely excess dye and does not represent denatured lipoprotein material. Proper separation was not achieved on 5 per cent polyacrylamide gel with samples of *HDL*<sub>2</sub> and *HDL*<sub>3</sub> which were dialysed against 1 M sodium chloride and undialysed *LDL*.

When 3.75 per cent polyacrylamide gel was used, prestained fractions (*LDL*, *HDL*<sub>2</sub> and *HDL*<sub>3</sub> dialysed against sodium chloride) resolved into several components as shown (Fig. 2). *LDL* entered the main gel but did

not resolve further. *HDL*<sub>2</sub> separated into 2 components near the top of the gel and 2 or 3 components in the lower part of the gel. Five components were observed with *HDL*<sub>3</sub>, but there was more of the fast and less of the slow components when compared with *HDL*<sub>2</sub>. When protein stain was used the patterns obtained with *HDL*<sub>2</sub> and *HDL*<sub>3</sub> were quite similar though not identical. With this stain, the slow components were resolved quite distinctly in both samples and, in the case of *HDL*<sub>3</sub>, 3 distinct fast components were observed (Fig. 3). Subsequent experiments have indicated that the faster of the slow components is *LDL*. From these data it would appear: (1) that *HDL*<sub>2</sub> isolated by standard preparative centrifugation contains small amounts of *LDL* (which is also present in trace amounts in *HDL*<sub>3</sub>); (2) that *HDL*<sub>2</sub> has a slower moving component (probably *HDL*<sub>1</sub>, *S*<sub>f</sub> 1.063, 0-3) not present in any appreciable amount in *HDL*<sub>3</sub>; and (3) that *HDL*<sub>2</sub> and *HDL*<sub>3</sub> both contain fast moving components of very similar electrophoretic mobilities. Moving boundary electrophoresis of *HDL* fractions was reported to have exhibited only one peak in all fractions and to have migrated with identical mobilities<sup>6</sup>. Starch-gel electrophoresis failed to resolve the *HDL* components<sup>6</sup>.

The flotation patterns of the three fractions are shown in Fig. 4. By analytical ultracentrifugation only one component was observed in the case of *LDL* and *HDL*<sub>2</sub>. It is possible there was a trace component floating ahead of the main peak in the case of *HDL*<sub>3</sub>. With *HDL*<sub>2</sub>, both at *d* = 1.125 and *d* = 1.21 (not shown in Fig. 4), at least 3 components were seen and their *S*<sub>f</sub> 1.125 (KBr-NaCl) values were observed to be 2.1, 14.3, and 18.4. These values were somewhat higher than those observed by Barclay<sup>3</sup> because of use of the KBr-NaCl medium rather than NaCl. It should be pointed out that the viscosity ratio of KBr solutions (over a range of 0.25-4.0 molar) to water at 25° is less than unity in contrast to most other salt solutions. If calculations are performed to determine the *S*<sub>f</sub> values at *d* = 1.125 (NaCl) of *LDL* (*S*<sub>f</sub> 3-10, *d* = 1.0635, NaCl) and *HDL*<sub>1</sub> (*S*<sub>f</sub> 0-3, *d* = 1.0635, NaCl) on the basis of their known partial specific volumes, the values obtained are respectively 17-58 and 0-16.5. Thus it would appear that the intermediate component seen in the centrifuge was apparently *HDL*<sub>1</sub> and was probably identical with the *HDL*<sub>2</sub> component possessing the lowest electrophoretic mobility. The fast component may represent a part of the spectrum of *LDL* species and may be tentatively identified as the faster of the two slow components observed by disk electrophoresis.

In a medium of density 1.21, *HDL*<sub>2</sub> exhibited a flotation pattern similar to that at *d* = 1.125. The *S*<sub>f</sub> value of the slow component of *HDL*<sub>2</sub> at *d* = 1.21 was 6.0 and was considerably higher than the *S*<sub>f</sub> value of *HDL*<sub>3</sub> (3.6), which is in agreement with the data of Lindgren and Nichols<sup>2</sup>. Therefore, it can be concluded that both *HDL*<sub>2</sub> and *HDL*<sub>3</sub> have components with very closely related electrophoretic mobilities but with different *S*<sub>f</sub> values.

Finally, as an application of this method, we have examined the disk electrophoretic patterns of prestained

sera from 6 individuals using 5 per cent and 3.75 per cent polyacrylamide gels. In Fig. 5, *D* 104-1, 2, 3 represent the sera obtained from coronary patients and *D* 104-4, 5, 6 represent the sera which we took from ourselves and which we presumed to be normal. The leading dense component in all cases was albumin, which appeared as a brown band and must be ignored for the present discussion. As before, gel concentrations of 5 per cent and higher did not permit the migration of *LDL*. In 5 per cent polyacrylamide gel, *HDL* separated into 2 components in all samples (Fig. 6). With 3.75 per cent gel concentration, *LDL* was better resolved but the high-density lipoproteins diffused rapidly. In the gel *D* 104-2, three

Fig. 4. Lipoprotein flotation patterns. Flotation left to right. (a) *LDL* in a medium of *d* = 1.063, 18 min after speed. (b) *HDL*<sub>2</sub> in a medium of *d* = 1.125, 19 min after speed. (c) *HDL*<sub>2</sub> in a medium of *d* = 1.21, 21 min after speed

Fig. 5. Disk-electrophoretic patterns of human sera. (Lipid pre-stain.) 3.75 per cent gel. D 104-1, 2, 3 coronary samples, D 104-5, 6, 7 normal samples. 10% each, 2.5 m.amp, 28 min

components could be very clearly seen in the low-density lipoprotein region. The high-density lipoproteins tend to fade rapidly, particularly in the 3.75 per cent gel. Photography of the gels is a difficult problem, and therefore the faint bands of HDL and the partially resolved bands of LDL which were visible in the gels were not clearly defined in the photographs. The large difference in the amount of LDL and the relatively higher amount of LDL to HDL observed visually in the two groups are evident from Fig. 5. The increased ratio of serum LDL/HDL has been related to atherosclerosis<sup>8</sup>, and the present method which requires smaller quantities of serum may find application in this direction. In summary, polyacrylamide-gel

electrophoresis provides better resolution of lipoprotein components than ultracentrifugal or other zone electrophoretic methods.

We thank Dr. Clarence Walton for the serum samples from coronary patients. We thank the Animal Nutrition Department, the Chemistry Department of the University of Illinois and Dr. A. Dravid of Galesburg State Hospital for facilities and use of the preparative and analytical ultracentrifuges. ## A VITAMIN D<sub>3</sub>-DEPENDENT FACTOR INFLUENCING CALCIUM BINDING BY HOMOGENATES OF CHICK INTESTINAL MUCOSA

By A. N. TAYLOR and PROF. R. H. WASSERMAN\*

Department of Physical Biology, New York State Veterinary College, Cornell University, Ithaca, New York

AN earlier report by us<sup>1</sup> described findings of an effect of vitamin D<sub>3</sub> on radiocalcium binding by chick mucosal homogenates. It was apparent from those investigations that the supernatant from duodenal tissue homogenates derived from vitamin D<sub>3</sub>-treated chicks (in contrast to rachitic controls) had the ability to decrease radiocalcium uptake by the cellular debris. It was also noted that the observed decrease was not due to citrate levels, pH or the protein binding capacity of the supernatant. The direct addition of vitamin D<sub>3</sub> to rachitic supernatant was without effect. In particular, it was determined that this phenomenon is associated with a factor in the vitamin D<sub>3</sub>-supernatant and not with some property of the cellular debris.

Investigations by DeLuca and Engstrom<sup>2</sup> and Brierly *et al.*<sup>3</sup> showed that calcium is accumulated by mitochondria via a process dependent on ATP, Mg<sup>++</sup>, phosphate ion and oxidizable substrate. Engstrom and DeLuca<sup>4</sup> reported that the uptake phase was not influenced by vitamin D whereas the release of calcium was

vitamin D-dependent. In the present investigations, the actual fraction accumulating calcium in the chick homogenates, and the substrate requirements for this process, have not yet been precisely determined. Therefore, the relationship between the mitochondria investigations and the present homogenate-binding experiments cannot be delineated.

This article describes additional observations concerning the substance, which appears to be a protein or a polypeptide, in the vitamin D<sub>3</sub>-supernatant, responsible for the decreased uptake of radiocalcium.

Homogenates were prepared in the following manner. Four-week-old chicks on a rachitogenic diet (General Biochemicals, Inc.) were given 500 i.u. of vitamin D<sub>3</sub> at 72 and 24 h before use; controls were given an equal volume of the carrier alone (cotton-seed oil). After decapitation the duodenum was quickly removed and placed in ice-cold saline, then on to a glass plate where it was slit open and rinsed with cold saline. The mucosal cell layer was stripped from the muscle layers using a glass slide and placed in cold buffer (tris-HCl 1.37 × 10<sup>-3</sup> M, sodium chloride 0.119 M, potassium chloride

\* Present address: Institute of Biological Chemistry, University of Copenhagen, Denmark (1964-65).

$4.47 \times 10^{-3}$  M, glucose  $9.85 \times 10^{-5}$  M, pH 7.2-7.4). A 20 per cent (w/v) homogenate was prepared using either a Potter-Elvehjem system with 'Teflon' pestle or a Virtis homogenizer. In earlier experiments radiocalcium ( $^{45}\text{Ca}$  or  $^{47}\text{Ca}$ ) with carrier (about  $1 \mu\text{g}/\text{ml}$  homogenate) was then added, and the homogenate mixed and centrifuged for 20 min in a refrigerated centrifuge at 38,000g. In work on the properties of the supernatant factor, the centrifugation was performed before calcium addition; the supernatants or fractions therefrom were recombined with freshly prepared homogenate precipitates, mixed, radiocalcium added and then centrifuged. The recombined homogenates were at the same concentration (20 per cent w/v) as in the original preparation. If  $^{45}\text{Ca}$  was used, an aliquot of the supernatant was dried on a planchet and counted with a thin-window Geiger-Müller tube; when  $^{47}\text{Ca}$  was used, the supernatant and precipitate fractions were both counted with a sodium iodide crystal using a single-channel analyser set to eliminate any contribution from  $^{47}\text{Sc}$ . All operations were carried out at  $4^\circ\text{C}$ . Protein was determined by the method of Lowry *et al.*<sup>5</sup>.

Initially, the effect of the dilution of vitamin  $\text{D}_3$  supernatant with rachitic supernatant on radiocalcium binding by the test system was determined. The resulting mixtures were recombined with freshly prepared rachitic debris before radiocalcium was added. From Fig. 1, it may be seen that there was a linear relationship between the proportion of  $\text{D}_3$ -supernatant in the system and the percentage of  $^{45}\text{Ca}$  remaining in the supernatant. The curve does not intersect the axis at zero, presumably because of the existence of some binding-depressing capacity in the rachitic supernatant. This explanation is based on the observation that when *tris* buffer replaces supernatant, 98-99 per cent of the radiocalcium is taken up<sup>1</sup>. The linear form of the relationship indicates that the test system would be suitable for assay purposes.

Investigations were first undertaken on the temperature stability of the unknown factor at pH 7.2-7.4. It was found to be completely stable at room temperature for 72 h and up to 5 days at  $4^\circ\text{C}$ . On heating in a water bath for 10 min, no decrease in activity was observed at  $69^\circ\text{C}$ , a 33 per cent decrease was seen at  $79^\circ\text{C}$  and complete inhibition at  $86^\circ\text{C}$ . At  $69^\circ\text{C}$ , a considerable amount of protein coagulated and could be removed by centrifuga-

Fig. 1. Linear relationship between vitamin  $\text{D}_3$ -supernatant concentration and percentage  $^{45}\text{Ca}$  remaining in supernatant. The  $\text{D}_3$ -supernatant was diluted with rachitic supernatant in the proportions given on the abscissa. The mixed supernatants were recombined with freshly prepared rachitic debris to the original concentration (20 per cent w/v). The debris was re-suspended,  $^{45}\text{Ca}$  added, mixed and centrifuged at 38,000g for 20 min. The entire procedure was done at  $4^\circ\text{C}$ . The values represent the mean  $\pm$  S.E. of 4 determinations.

Fig. 2. Correlation of vitamin  $\text{D}_3$ -supernatant factor with protein in gel filtration fractions. Elution was performed with de-ionized water at a rate of 0.4 ml. per min through 'Sephadex G-25' ( $1 \text{ cm} \times 50 \text{ cm}$ ).

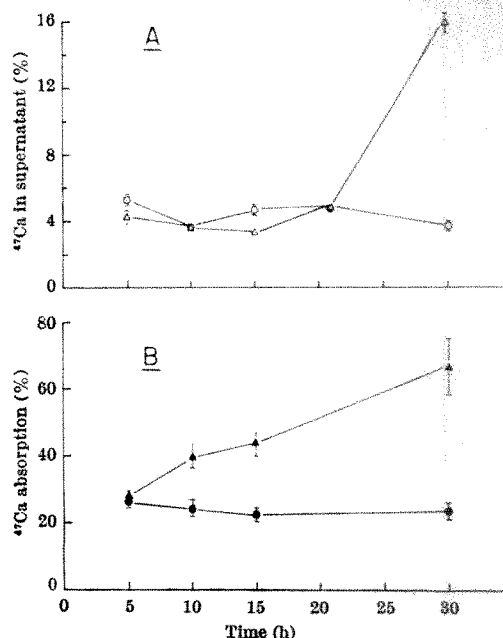

Fig. 3. Time relationship between appearance of supernatant factor and calcium absorption after vitamin  $\text{D}_3$  administration. A, percentage  $^{45}\text{Ca}$  remaining in supernatants from rachitic (○) and vitamin  $\text{D}_3$  (Δ) homogenates. *In vitro* test system as described in text. Values represent mean  $\pm$  S.E. of 5 determinations. B, absorption of  $^{45}\text{Ca}$  from ligated segments of chick duodenum *in vivo*. Period of absorption was 1 h. ●, rachitic; ▲, vitamin  $\text{D}_3$ . Experimental details given in ref. 6. Values represent mean  $\pm$  S.E. from 5 chicks.

tion; this affected about a 2-3-fold purification of the supernatant factor.

When the vitamin  $\text{D}_3$ -supernatant was dialysed against de-ionized water for 20 h, there was no appreciable loss of activity although some proteins precipitated from the solution. This indicated that the factor was of relatively large diameter or was associated with macromolecules.

Although the above evidence suggested that the factor may be protein in nature, additional information was sought by using gel filtration. Supernatant fluid was placed on a 'Sephadex G-25' column and eluted with de-ionized water. Pooled fractions were assayed for: (a) their ability to decrease radiocalcium binding by chick homogenates; (b) protein content; (c) conductivity (salt concentration). These results are depicted in Fig. 2. It may be seen that, as expected, the protein fraction preceded the electrical conducting substances. The supernatant factor was largely associated with the

protein or polypeptide fraction. As the protein concentration decreased, the concentration of the factor similarly decreased.

Since the presence of the supernatant factor in mucosal homogenates is dependent on vitamin D<sub>3</sub>, the question arises as to its importance in the gastrointestinal absorption of calcium. A time-dependent examination was therefore done to determine when the factor is formed in relation to when one sees a positive effect of vitamin D<sub>3</sub> on calcium absorption *in vivo*. Chicks were dosed with vitamin D<sub>3</sub> (500 I.U.) or carrier alone at periods of from 5 to 30 h before use. Half each treatment group was then used in a ligated-duodenum experiment<sup>6</sup> with <sup>45</sup>Ca to determine absorption *in vivo*. The other half were killed, and mucosal homogenates prepared for the <sup>45</sup>Ca binding examination as described here. Fig. 3 shows that the *in-vivo* effect of vitamin D<sub>3</sub> on calcium absorption is observable between 5 and 10 h after sterol administration, whereas the *in-vitro* system fails to show a response until 30 h.

This would suggest that either (a) the vitamin D<sub>3</sub>-supernatant factor does not play a primary part in calcium absorption, or (b) the factor may be initially in a bound form and not immediately released into the supernatant fluid. However, since the concentration of the unknown factor in mucosal tissue is dependent on vitamin D<sub>3</sub> and this factor does influence calcium metabolism, it may function in a more subtle manner on absorption than as determined here.

Recently D. Schachter (personal communication) observed that puromycin inhibited the vitamin D-stimulated oxygen-dependent uptake of calcium by rachitic rat duodenum. Edelman *et al.*<sup>7</sup> proposed the hypothesis that another steroid, aldosterone, "regulates active sodium transport by increasing *de novo* synthesis of enzymes involved in supplying energy for transport work"

in the urinary bladder of *Bufo marinus*. Olson<sup>8</sup> observed an antagonism by actinomycin D of the vitamin K-induced prothrombin formation and suggested the possibility that all the fat-soluble vitamins operated to control the synthesis of specific proteins and enzymes.

In this article the formation of a vitamin D-stimulated factor, presumably a protein or a polypeptide, is described which may have an important function in calcium movement. Whether vitamin D acts at the gene level or on some other phase of protein synthesis cannot yet be determined on the limited evidence available. Further, it is possible that the supernatant factor is an indirect consequence of the general influence of vitamin D on metabolism.

This work was supported by grant AM-04652 from the U.S. National Institutes of Health.

*Note added in proof.* Pertinent here are the very recent observations of R. Eisenstein and M. Passavoy (*Proc. Soc. Exp. Biol. and Med.*, 117, 77; 1964). It was reported that actinomycin D inhibited the hypercalcaemia induced in mice and rats by large doses of vitamin D or parathyroid hormone, indicating that the latter agents may act by inducing the synthesis of new enzymes in bone through a DNA-directed RNA system. Present experiments in our laboratory also showed that actinomycin D prevented the stimulation of calcium absorption by vitamin D<sub>3</sub> in rachitic chicks.

## INHIBITION INVESTIGATIONS WITH THE *Hi* AGGLUTINOGEN OF CHICKEN ERYTHROCYTES

By DR. S. L. SCHEINBERG and R. P. RECKEL\*

Animal Husbandry Research Division, Agricultural Research Service, U.S. Department of Agriculture

**A**N extract of *Pisum arvense*, the Canadian field pea, detects the presence of an agglutinin in chickens designated *Hi*. Normally, the *Hi* substance is found only in females which possess the *Hi* gene and which are sexually mature. The latter feature is due to the association of the *Hi* agglutinin with the female hormone, oestrogen. Injection of diethylstilboestrol into genetically competent males or young chickens results in the expression of the *Hi* substance in these birds as well<sup>1-3</sup>.

Progesterone, methyl testosterone or corn oil, the hormone solvent, injected at the same levels as diethylstilboestrol, did not stimulate the production of the agglutinin. Nor does testosterone have any residual effect, for diethylstilboestrol evokes the appearance of the *Hi* substance even when used after a course of injections with testosterone. Both males and females have been given continuous injections of a polyethylene glycol paste preparation of diethylstilboestrol subcutaneously, some for as long as 32 months. The titres of these birds, once they reached their maximum levels, did not diminish during this period, and these birds have been used as the standards for the experiments.

At the outset of these experiments, it was found possible to inhibit the agglutination reaction between the red cell and *Pisum arvense* extract. This discovery permitted examinations to be made on the nature of the *Hi*

substance and on the bonding between the agglutinin and the agglutinin.

Tests for inhibition were performed by mixing aliquots of lectin and the potential inhibitor and allowing these to incubate for 10 min at 22° C. An aliquot of a standard 2 per cent red cell suspension was then added and the mixture shaken and incubated for an additional 5 min. The tubes were then centrifuged (1,650g, 1 min) and scored macroscopically for the presence of agglutination; the score for maximum agglutination was four, with lesser scores for decreasing amounts of agglutination. All weak and zero readings were checked microscopically.

Tests for inhibition were conducted on more than 91 compounds. They included 21 amino-acids, 6 proteins, 13 hormones and more than 51 carbohydrates. Thyrotropin and a number of sugars were found to be inhibitory. All other substances tested failed to inhibit. Substances were tested for their inhibitory capacity using a 0.4 M solution. Those substances which when tested at this concentration resulted in 100 per cent inhibition were regarded as inhibitory; those substances which did not inhibit maximally at this concentration were deemed non-inhibitory. The smallest amount of a substance necessary for inhibition was determined by using successive dilutions of the inhibitor until inhibition could no longer be detected.

\* Present address: Ortho Research Foundation, Raritan, New Jersey.

Fig. 1. Mixed agglutination of human and chicken erythrocytes

Human cells are completely cross-reactive with chicken cells in respect to *Pisum arvense*. This circumstance provided the opportunity for a mixed agglutination system in which human cell detectors form rosettes on chicken red cells coated with *Pisum arvense* (Fig. 1), the presence or absence of agglutination being detected by microscopic examination. The minimum amount of D-glucose<sup>4</sup> required for inhibition in this system was 0.13%, whereas the minimum amount in the conventional system was 2.1%. The use of the mixed agglutination procedure permitted an estimate of the amount of D-glucose<sup>4</sup>, a non-inhibitor, needed for inhibition. It was found that at least 90% of D-galactose was needed for inhibition.

The results of inhibition experiments with monosaccharides indicate that those in which the C<sub>3</sub> and C<sub>4</sub> hydroxyls are in the *trans* position have the capacity to inhibit the agglutination of *Hi* containing red cells with *Pisum arvense*. In the Haworth symbolism the C<sub>3</sub> hydroxyl is in the up position and the C<sub>4</sub> hydroxyl is in the down position. In this group are the sugars shown in Table 1. The amount indicated is for complete inhibition in the test tube, using 0.05 c.c. of agglutinin, 0.05 c.c. of the inhibitor solution and 0.05 c.c. of a standard 2 per cent red cell suspension. If the C<sub>3</sub> and C<sub>4</sub> hydroxyl groups are in the *cis* position and down, there is no inhibition. In this category are D-allose and D-altrose. If the C<sub>3</sub> and C<sub>4</sub> hydroxyl groups are in the *cis* position and up, there is no inhibition. In this group were D-galactose and  $\alpha$ -D-talose. A sugar in which the C<sub>3</sub> and C<sub>4</sub> hydroxyls were the reverse of that in D-glucose,  $\beta$ -L-glucose, did not inhibit.

Table 1. MONOSACCHARIDES WITH THE C<sub>3</sub> AND C<sub>4</sub> HYDROXYLS IN *trans* CONFIGURATION

D-fructose-( $\beta$ -D-fructofuranose) <sup>5</sup> —3.6 mg	2-deoxy-D-glucose—1.8 mg
1,5-anhydro-D-glucitol—1.8 mg	$\alpha$ -D-glucose <sup>4</sup> —1.8 mg
D-glucosamine <sup>6</sup> —3.6 mg	3-O-methyl-D-glucose—0.45 mg
N-acetyl-D-glucosamine <sup>6</sup> —3.6 mg	1,5-anhydro-D-mannitol—1.8 mg
methyl $\alpha$ -D-glucoside—1.8 mg	$\alpha$ -D-mannose <sup>4</sup> —0.9 mg
$\beta$ -D-glucose <sup>4</sup> —3.6 mg	methyl $\alpha$ -D-mannoside—0.9 mg

Inhibition experiments were carried out to determine which hydroxyl groups might be involved in combination with the agglutinin. Substitutions involving the C<sub>1</sub> hydroxyl did not alter the inhibition properties of the hexose. The following were tested and all inhibited: methyl- $\alpha$ -D-glucoside<sup>5</sup>, 1,5-anhydro-D-mannitol, methyl- $\alpha$ -D-mannoside, D-glucose 1-phosphate<sup>6</sup> and 1,5-anhydro-D-glucitol.

Substitutions involving the C<sub>2</sub> hydroxyl likewise did not alter the capacity of the hexoses to inhibit. Included in this group were D-fructose, D-glucosamine, N-acetyl-D-glucosamine and 2-deoxy-D-glucose. Substitutions for the C<sub>3</sub> hydroxyl also resulted in inhibition; the sugars tested were 3-O-methyl-D-glucose and D-glucose 3-sulphate.

The C<sub>5</sub> hydroxyl is not involved, since only the ring forms of the hexoses inhibit. D-Mannitol and D-glucitol<sup>4</sup>

do not inhibit, whereas the 1,5-anhydro derivatives of both do.

The C<sub>4</sub> hydroxyl group was substituted with the 4-O-methyl-D-glucose which failed to inhibit. Prior to testing with this sugar, we suspected that the C<sub>4</sub> hydroxyl was involved in the inhibition.  $\alpha$ -D-Glucose pentaacetate<sup>5</sup> and methyl  $\beta$ -D-glucopyranoside tetraacetate which possessed ring structures failed to inhibit; since we had already excluded the C<sub>1</sub>, C<sub>2</sub> and C<sub>3</sub> hydroxyls, then the fourth was implicated. The necessity for the C<sub>3</sub> and C<sub>4</sub> hydroxyls to be in the *trans* position likewise suggested that the C<sub>4</sub> hydroxyl was involved, and the inhibition experiment with 4-O-methyl-D-glucose confirmed this. More recently, another C<sub>4</sub> substituted hexose has become available, that is, dicyclohexyl ammonium salt of methyl  $\alpha$ -D-glucopyranoside 4-(dihydrogen) phosphate; this compound likewise failed to inhibit.

As a test of the influence of the C<sub>6</sub> hydroxyl, the disodium salt of glucose 6-phosphate<sup>6</sup> was used, and it failed to inhibit, implicating the C<sub>6</sub> hydroxyl group in the inhibition. Previous experiments with the barium salt of glucose 6-phosphate had been ambiguous; consequently, when the disodium salt became available, it was quickly tested. Solubility and pH of the prospective inhibitors were always matters of concern and occasionally limited for a time the testing of a particular compound. Confirmation of the role of the C<sub>6</sub> hydroxyl group came from tests with other C<sub>6</sub> substituted hexoses: 6-deoxy-6-O-nitro-D-glucose and dicyclohexyl ammonium salt of methyl D-glucoside 6-(dihydrogen) phosphate, and the same salt of methyl D-mannoside 6-(dihydrogen) phosphate; all these compounds failed to inhibit the reaction.

Pentoses had been tested in our initial survey, and had uniformly failed to inhibit the agglutination reaction. Their lack of a sixth hydroxyl group may be suspected as the basis for their uniform behaviour. Nine pentoses, as well as one tetrose and one triose, were tested and all failed to inhibit. These were L-arabinose, D-arabinitol<sup>3</sup>, L-arabinitol<sup>4</sup>, erythritol, D,L-glyceraldehyde<sup>6</sup>,  $\alpha$ -D-lyxose, 2-deoxy-D-ribose, D-ribose, D-xylitol, D-xylose, and methyl- $\beta$ -D-xyloside.

Based on the findings with monosaccharides, it was possible to make predictions regarding the inhibition with oligosaccharides. In order to inhibit, an oligosaccharide must possess at least one hexose residue with the C<sub>3</sub> and C<sub>4</sub> hydroxyl groups in the *trans* position and the C<sub>4</sub> and C<sub>6</sub> hydroxyl must be neither substituted nor involved in the linkage between residues. Oligosaccharides with more than one residue possessing the necessary properties would be expected to inhibit to a greater extent than the standard D-glucose. At the outset it was necessary to make one additional assumption based on our observations with sophorose, and that was that  $\beta$ -linkages result in a reduction of inhibition.

Listed next are comparisons between expectation and observation, with the reasons for the expectation given in parenthesis after each compound. The following compounds were not expected to inhibit and did not: cellobiose and epicallobiose (linkage involves C<sub>4</sub> of second residue,  $\beta$ -linkage); cellobiose (second residue is altrose,  $\beta$ -linkage); lactose<sup>4</sup> (first residue is galactose, linkage involves C<sub>4</sub> of second residue,  $\beta$ -linkage);  $\beta$ -gentiobiose (linkage involves C<sub>6</sub> of second residue,  $\beta$ -linkage); melibiose<sup>4</sup> (first residue is galactose, linkage involves C<sub>6</sub> of second residue); primeverose (first residue is xylose, linkage involves C<sub>6</sub> of second residue,  $\beta$ -linkage); the trisaccharide raffinose<sup>6</sup> (first residue is galactose, linkage involves C<sub>6</sub> of second residue,  $\beta$ -linkage between second and third residues); and the polysaccharides dextran (linkages between residues mainly involve C<sub>4</sub> with some C<sub>6</sub>); inulin ( $\beta$ -linkages between residues); starch (linkages involve C<sub>6</sub> for amylose and C<sub>4</sub> for amylopectin).

The following disaccharides containing two glucose residues were expected to inhibit to the same extent as the standard D-glucose, and this was found to be the

case with the reason for the expectation given in parenthesis: maltose<sup>4</sup> (linkage involves C<sub>4</sub> of second residue), sucrose<sup>4</sup> ( $\beta$ -linkage).

Because the following compounds contained two or more inhibiting residues and no prohibitive linkages, they were expected to inhibit to a greater extent than the standard D-glucose: trehalose (D-glucose, 1.35 mg; trehalose, 0.63 mg); turanose (D-glucose, 1.35 mg; turanose, 0.63 mg); melezitose (a trisaccharide possessing three inhibiting residues but also a  $\beta$ -linkage; D-glucose, 1.35 mg; melezitose, 0.45 mg).

The results of these comparisons confirm the results already obtained with monosaccharides. Mannose or a mannose-like monosaccharide is an important part of the agglutinin, and the linkage between it and *Pisum arvense* involves the C<sub>4</sub> and C<sub>6</sub> hydroxyl groups.

We thank the following for their contributions of monosaccharides and oligosaccharides: Dr. H. C. Fletcher and Dr. N. K. Richtmeyer (D-allose, D-altrose, L-arabinose, D-arabitol, cellobiose, cellobiose, dulcitol, epicallobiose, erythritol,  $\alpha$ -gentiobiose, 1,5-anhydro-D-glucitol, methyl- $\beta$ -D-glucopyranoside tetraacetate,  $\beta$ -L-

glucose, 2-deoxy-D-glucose, 3-methyl- $\alpha$ -D-glucose, inulin,  $\alpha$ -DL-lyxose, 1,5-anhydro-D-mannitol, methyl- $\alpha$ -D-mannoside, melezitose, primeverose, 2-deoxy-ribose, sophorose,  $\alpha$ -D-talose, trehalose, turanose, D-xylitol, L-xylitol, methyl- $\beta$ -D-xyloside); Prof. Fred Smith (4-O-methyl-D-glucose); Dr. Patricia Szabó (dicyclohexyl ammonium salt of methyl  $\alpha$ -D-glucopyranoside 4-(di-hydrogen) phosphate, of methyl glucoside-6-(di-hydrogen) phosphate, and of methyl  $\alpha$ -D-mannoside-6-(di-hydrogen) phosphate); Dr. F. W. Lichtenthaler (6-deoxy-6-nitro-D-glucose); Dr. J. R. Turvey (D-glucose-3-sulphate). We also thank Dr. D. T. O. Wong and Dr. N. K. Richtmeyer for their advice.

## CLEARANCE OF PARTICULATE MATTER FROM THE TRACHEOBRONCHIAL TREE IN PATIENTS WITH TUBERCULOSIS

By PROF. HENRY N. WAGNER, jun., DR. VINCENT LOPEZ-MAJANO and JAMES K. LANGAN

Departments of Medicine and Radiological Science, Johns Hopkins University School of Medicine and Veterans Administration Hospital, Baltimore, Maryland

THE importance of physiological mechanisms for clearing dust and other particulate matter from the lungs and tracheobronchial tree is illustrated by the fact that, while a coal miner may in his lifetime inhale 6,000 g of coal dust particles less than  $4\mu$  in size, only 100 g will be found in his lungs at post-mortem examination<sup>1</sup>. In a typical English industrial town, a person inhales about 100 g of carbon during a lifetime, but only 0.5–1.0 g are found in his lungs and bronchial glands at autopsy<sup>2</sup>. From experimental investigations of the behaviour of particulate matter in the respiratory tract, it is known that larger particles,  $10\mu$  or more in size, are trapped in the nose, while smaller particles penetrate farther into the lungs and settle on the mucous blanket lining the tracheobronchial tree<sup>3</sup>. About 90 per cent of particles less than  $1\mu$  in size penetrate through to the lungs.

One mechanism by means of which foreign particles are eliminated from the lungs is the activity of cilia which line the bronchial tree as far down as the respiratory bronchioles. Riding on the mucous blanket which covers the cilia, particles are propelled up to the oropharynx, where they are swallowed. A second mechanism is coughing. In the past, quantitative investigation of these mechanisms to determine their relative importance and degree of derangement under various physiological and pathological conditions has been difficult, particularly in human subjects. Recent advances in the field of external radiation detectors combined with the ability to label a variety of particles with  $\gamma$ -emitting radioactive isotopes have made possible a new approach to these problems. This article describes results obtained in the examination of patients with a chronic pulmonary disease, namely, pulmonary tuberculosis.

During the past few years we have used aggregates of human serum albumin labelled with iodine-131 as a type of particulate matter suitable for investigation of the phagocytic capacity of the reticulo-endothelial system<sup>4–7</sup>. Details of the method of preparation of the particles are given elsewhere<sup>4</sup>. In essence, aggregation of human serum albumin was produced by heating under controlled conditions of pH, temperature and shaking. The mean molecular weight of the final particle, measured by the light-scattering method, indicated that an average of 11 albumin molecules had aggregated, although the size

Fig. 1. Scan of the distribution of aggregated albumin particles 53 min after their injection into the lung through a catheter extending into the right main bronchus. On the right the catheter can be seen in the X-ray of the chest

Fig. 2. Serial scans of the distribution of aggregated albumin particles. The numbers 0, 29 and 58 refer to the time (min) after injection of the particles into the right main bronchus. The area of increased radioactivity in the scan performed 29 min after injection of the particles was at the carina. The lower graph indicates the time course of radioactivity at the carina. At point A the patient coughed and the amount of radioactivity increased suddenly, presumably the result of particles being propelled upward to the carina. Thereafter the radioactivity decreased up to point B where the patient again coughed. This resulted in a further increase in activity; at point C the patient again coughed and the amount of radioactivity fell precipitously. The final decrease in activity occurred at 48 min and was also due to a cough.

Fig. 3. Serial scans of the distribution of aggregated albumin particles after injection into the right main bronchus. The numbers 0, 5 and 23 indicate the time (min) that the scan was begun after injection of the particles. The lower graph is the time course of radioactivity as measured by a stationary radiation detector at the lower end of the area of maximum radioactivity.

of the particles was quite variable. Their mean size was about 100 Å. When injected intravenously, the albumin aggregates were removed from the blood by the reticulo-endothelial system, as evidenced by the kinetics of their removal from blood, their localization in the macrophages of the liver and spleen, and their effect in producing transient blockade of the reticulo-endothelial system. Large doses of these particles could be given repeatedly over prolonged periods of time to human subjects without evidence of hypersensitivity or excessive radiation. An advantage of albumin aggregates over the other colloidal particles, such as carbon, thorium dioxide ('Thorotrast'), saccharated iron oxide, radioactive chromic phosphate, colloidal gold or colloidal silver, is that these particles are metabolized after they are ingested by phagocytic cells

and therefore do not remain in the body for long periods of time. An additional advantage is that the appearance of radioactivity in the blood in the form of iodide ion can be used as an indication that the particles have been ingested by phagocytic cells.

In the work recorded here 0.1–0.3 ml. of a solution containing less than 0.1 mg of aggregated albumin labelled with 20–100 µc. iodine-131 was injected at various positions along the tracheobronchial tree in man by means of a fine radiopaque catheter inserted through a needle in the crico-thyroid membrane. Local anesthesia was used at the site of injection, but no other medication was necessary. The patients lay quietly in the supine position.

The rate and pattern of movement were measured in two ways, by means of serial radioisotope scanning of the chest<sup>8</sup> and by means of two stationary crystal scintillation detectors with slit collimators (3.0 × 0.3 cm). Fifteen investigations were carried out in afebrile male patients with chronic pulmonary tuberculosis in various stages of activity at the time of the work. The thyroid gland was blocked with 0.5 ml. of Lugol's solution because of eventual deiodination of the albumin aggregates.

Fig. 1 illustrates the position of the catheter in the right lung of one patient. The scanning image of the distribution of the particles was obtained in this work 53 min after injection of the albumin aggregate particles. The large area of increased activity at the most distal point remained unchanged for as long as 2 h, presumably because of the location of the particles in alveoli or terminal bronchioles where cilia are absent. The rest of the particles lining the bronchi were moved slowly toward the larynx at a rate of approximately 1–2 cm/min.

In many patients, foci of accumulation of the particles were observed to form as the particles moved. Most often these were at the carina, but also in other regions along the tracheobronchial tree. An example is shown in Fig. 2. The graph in the lower part of the figure represents the rate of clearance of the radioactivity, as measured by a detector at the carina. There was a net decrease in concentration of radioactivity as the particles were being moved by ciliary activity. At point A the patient coughed, with the result that the particles moved from lower in the tracheobronchial tree up to the carina; ciliary activity then moved the particles at a steady rate for approximately the next 20 min; then, at point B, the patient coughed a large number of particles up to the carina, followed by another cough at point C, which resulted in a great decrease in activity, related to movement of the particles up to the oropharynx. Serial scans performed at the times designated by the numbers (minutes after the injection of the particles) gave a visual image of the processes being monitored with the stationary detectors.

In the patient shown in Fig. 3 the second scan shows a typical focal concentration of radioactivity. The tracing at the bottom of the figure was obtained by a stationary detector over the lower end of the area of distribution of the albumin aggregate particles. In this patient there

was a continual decrease in concentration of the radioactivity, presumably entirely due to ciliary activity since the patient did not cough throughout the examination. In all subjects the radioactivity could be detected eventually in the stomach, arriving there when the particles in the oropharynx were swallowed. Insignificant amounts of radioactive iodine were detectable in the blood until after the particles had been swallowed, thus indicating that the phagocytic process did not participate significantly in the movement of the particles up the tracheobronchial tree to the pharynx.

LaBelle and Brieger have reported that the physiological events following the intratracheal injection of particulate matter are the same as those seen after the inhalation of the same particles<sup>9</sup>. Consequently we chose to use this simple method in our initial investigations. The effect of ciliary activity and cough could be readily quantified. Both were of considerable importance in clearing the lungs of this type of particle. Examinations of other types of particle are in progress.

The frequent finding of areas of decreased ciliary activity where the particles seem to gather is of interest since these may indicate areas where cilia or ciliated cells have been

destroyed or where changes of the type described by Hilding may be found. He reported areas of squamous epithelial cells scattered throughout the lower respiratory tract, particularly at the carina<sup>10</sup>. It has been known for many years that islands of metaplasia of ciliated columnar epithelium result from chronic inflammation. In these areas squamous epithelium replaces the ciliated, mucous-covered epithelium, and the regions of diminished motility may correspond to such areas.

## REACTION OF THE RHODOPSIN CHROMOPHORE WITH SODIUM BOROHYDRIDE

By DERIC BOWNDS and PROF. GEORGE WALD

Biological Laboratories of Harvard University, Cambridge, Mass.

THE visual pigment, rhodopsin, is composed of a protein, opsin, bearing as chromophore the 11-*cis* isomer of retinal (vitamin A aldehyde, formerly retinene). Irradiation of this pigment isomerizes retinal from the 11-*cis* to the all-*trans* configuration, yielding as first product pre-lumirhodopsin ( $\lambda_{\max}$  543 m $\mu$ ). This is transformed in the dark via a series of transient intermediates, ending with the hydrolysis of retinal from opsin<sup>1</sup>. The transition up to this last step goes very quickly at room temperature, but can be blocked at any stage by cooling. Pre-lumirhodopsin is stable below -140° C; above this temperature it goes to lumirhodopsin ( $\lambda_{\max}$  500 m $\mu$ )<sup>2</sup>. Above -40° C lumirhodopsin yields metarhodopsin I ( $\lambda_{\max}$  478 m $\mu$ ) which, at temperatures higher than -15° C, enters into tautomeric equilibrium with metarhodopsin II ( $\lambda_{\max}$  380 m $\mu$ ), rise in temperature and acidity favouring the proportion of metarhodopsin II. Above 0° C, metarhodopsin II hydrolyses to a mixture of opsin and all-*trans* retinal ( $\lambda_{\max}$  387 m $\mu$ )<sup>3</sup>.

In rhodopsin retinal appears to be bound to the protein in a Schiff base linkage:  $C_{19}H_{27}CH=O + H_2N\text{-opsin} \rightarrow C_{19}H_{27}CH=N\text{-opsin} + H_2O$ . Evidence for this formulation has come from the work of Collins<sup>4</sup> and Morton and Pitt<sup>5</sup>. The latter workers have investigated the acid denaturation product of rhodopsin (the conjugate acid of N-retinylidene-opsin,  $\lambda_{\max}$  440 m $\mu$ ), a protonated Schiff base between retinal and denatured opsin ( $C_{19}H_{27}CH=N^+H\text{-opsin}$ ). Having found from model reactions that Schiff base formation does not occur readily at acid pH, they concluded that the Schiff base linkage had been present in rhodopsin itself before denaturation. Collins has shown that irradiation of a rhodopsin solution at pH 9 in the presence of excess formaldehyde results in the formation of the non-protonated Schiff base of retinal at the chromophoric site (N-retinylidene-opsin), all the other available amino-groups on opsin having been complexed with formaldehyde. This suggests again that the Schiff base was present in rhodopsin before irradiation. (Following Morton and Pitt, we will use the term N-retinylidene-opsin for the Schiff base derivative of rhodopsin in which retinal is attached to denatured opsin at its original site. Alkaline

indicator yellow is then the random collection of Schiff bases which forms in strongly alkaline solution between liberated retinal and all available amino-groups of denatured opsin.)

Morton *et al.* have also examined the properties of Schiff bases of retinal with a variety of amino-acids and amines<sup>6-8</sup>. The Schiff bases of retinal have  $\lambda_{\max}$  about 367 m $\mu$ ; in acid solution they are protonated to form the conjugate acids, with  $\lambda_{\max}$  440-450 m $\mu$ . Hubbard has proposed that in rhodopsin the Schiff base linkage is protonated, and that the further shift of spectrum toward the red in this pigment (to  $\lambda_{\max}$  500 m $\mu$ ) is associated with side-chain interactions between retinal and the chromophoric site on opsin<sup>9</sup>. Such exaltation of spectrum persists throughout the intermediates of bleaching of rhodopsin, to the stage metarhodopsin II; so that one should assume that up to this stage these pigments are not only protonated Schiff bases, but also exhibit the close fit between retinal and opsin that permits bathochromic interaction. In the transition metarhodopsin I  $\rightarrow$  metarhodopsin II, the proton is presumably lost from the Schiff base linkage, and the side-chain interaction of retinal with opsin also is greatly decreased.<sup>3</sup>

If the foregoing picture is correct, it should be possible to hydrogenate the Schiff base linkage between retinal and opsin to produce a secondary amine at the chromophoric site. The hydrogenated linkage should be stable to hydrolysis, and thus should enable one to isolate retinal still attached to the group to which it is bound in native rhodopsin.

The most appropriate reagent for such a reduction is sodium borohydride, first used in enzyme investigations by Fischer *et al.* to reduce the Schiff base linkage between pyridoxal phosphate and muscle phosphorylase<sup>10</sup>. The borohydride reduction has since been applied to the examination of another pyridoxal phosphate enzyme, glutamic-aspartic transaminase<sup>11</sup>, and to examine the site of binding of the substrate (dihydroxy-acetone) to transaldolase<sup>12</sup>, and of acetoacetate to its decarboxylase<sup>13</sup>. The reactions of borohydride with other linkages found in proteins have not been thoroughly investigated; but

it is known to reduce disulphide bonds and occasionally to cleave peptide bonds<sup>14</sup>.

Cattle rhodopsin, prepared by a modification of methods previously used in this laboratory<sup>3</sup>, was reacted with a thousand-fold molar excess of powdered sodium borohydride. The pH was adjusted to desired values with small volumes of 0.1 N NaOH or HCl, and the pH did not vary by more than 0.2 during an experiment. The reactions were run at constant temperature in the Cary recording spectrophotometer, and spectra were measured periodically.

Rhodopsin itself does not react with sodium borohydride, nor is its absorption spectrum changed by the addition of this reagent between pH 3 and 9. However, when rhodopsin (Fig. 1, curve 1) is irradiated in the presence of sodium borohydride, a new compound appears (Fig. 1, curve 2) with  $\lambda_{\max}$  333 m $\mu$ , near that of retinol (vitamin A,  $\lambda_{\max}$  328 m $\mu$ ). Like retinol, this product exhibits brilliant green fluorescence.

Fig. 1. The reaction of rhodopsin with sodium borohydride during its bleaching by light. Curve 1 is the spectrum of cattle rhodopsin in 2 per cent digitonin, M/15 phosphate buffer, pH 8. Curve 2 was recorded after the solution had been irradiated at 578 m $\mu$  in the presence of sodium borohydride.

A possible interpretation of these results might be that irradiation yielded free retinal which was afterwards reduced to retinol by the sodium borohydride (cf. ref. 15). To examine this possibility, methanol was added to the solution to a concentration of 60 per cent, to precipitate protein and liberate any carotenoid not covalently bound, and the mixture was extracted four times with petroleum ether, which should extract any free retinol. The petroleum ether extract was washed three times with water, transferred to chloroform, and the antimony trichloride reaction used to determine the amount of retinol present. Fig. 2a shows that no significant colour reaction was obtained. The reduction product therefore was not retinol.

This was shown further by a parallel control experiment in which rhodopsin was bleached by light and left 1.5 h in the dark to allow retinal to hydrolyse off completely. Sodium borohydride was then added to reduce the retinal to retinol, and the mixture treated with methanol and extracted as before. When this extract was mixed with antimony chloride, the deep blue colour and absorption band at 620 m $\mu$  characteristic of retinol were obtained (Fig. 2b).

These experiments show that the product of bleaching rhodopsin in the presence of sodium borohydride is not retinol but the reduced Schiff base in which retinal is still bound to opsin at the chromophoric site:

We shall call this compound N-retinyl-opsin.

The products of treating rhodopsin with strong acid or alkali are, respectively, protonated and non-protonated Schiff bases of retinal with denatured opsin (the conjugate acid of N-retinylidene-opsin, and alkaline indicator

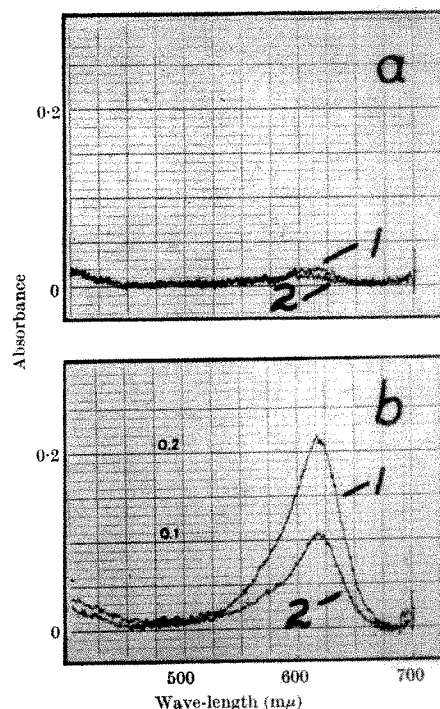

Fig. 2. Antimony chloride tests with reduced products of bleaching rhodopsin. (b) The retinal liberated on bleaching rhodopsin with light can afterward be reduced to retinol (vitamin A) with sodium borohydride. Such retinol is readily extracted with petroleum ether; mixed with antimony chloride it yields a blue colour owing to an absorption band with  $\lambda_{\max}$  620 m $\mu$  (curve 1 recorded 15 sec after mixing, curve 2 one min later). (a) Rhodopsin bleached in the presence of sodium borohydride, however, does not liberate retinol, as shown by the failure of this test in a similar extract of the solution that yielded spectrum 2 in Fig. 1. The reduction product in this experiment involves retinal still attached to opsin at the chromophoric site.

yellow)<sup>5</sup>. When sodium borohydride is added to alkaline indicator yellow, produced by irradiating a solution of rhodopsin at pH 9 (Fig. 3, curve 2), a derivative with  $\lambda_{\max}$  about 330 m $\mu$  appears immediately (Fig. 3, curve 3). Since alkaline indicator yellow is thought to be a random collection of Schiff bases between retinal and various amino-groups of opsin<sup>5</sup>, the reduction has probably fixed retinal on to several different amino-groups. Here again, the reaction mixture, extracted as described above, contained no free retinol or retinal, as shown by the complete absence of an antimony trichloride reaction. This was true also in all the further experiments to be described.

Fig. 4 shows the reduction of the product of acid denaturation of rhodopsin, the protonated N-retinylidene-opsin, in which retinal is thought to be still attached to

Fig. 3. The reduction of alkaline indicator yellow with sodium borohydride. Rhodopsin (curve 1) is irradiated at pH 9 to produce alkaline indicator yellow (curve 2,  $\lambda_{\max}$  367 m $\mu$ ). Sodium borohydride is then added to reduce the multiple Schiff base linkages between retinal and amino-groups on opsin (curve 3,  $\lambda_{\max}$  330 m $\mu$ ).

Fig. 4. The reduction of N-retinylidene-opsin with sodium borohydride. A rhodopsin solution (curve 1) is brought to pH 1 in the dark, acid-denaturing the rhodopsin to yield the conjugate acid of N-retinylidene-opsin ( $\lambda_{\max}$  440 m $\mu$ ). After raising the pH to 4 (curve 2), sodium borohydride is added. This reduces the N-retinylidene-opsin to (denatured) N-retinyl-opsin (curve 3).

its original site in native rhodopsin. Rhodopsin is brought to pH 1 and then to pH 4 (curve 2) before adding sodium borohydride. This is done because at pH 4 sodium borohydride is decomposed by hydrolysis less rapidly than at pH 1, yet the Schiff base remains protonated. The spectrum of the reduced derivative appears immediately after the addition of sodium borohydride and is similar in shape and absorption maximum to that obtained when rhodopsin is bleached in the presence of sodium borohydride (curve 3).

Protonated and non-protonated Schiff bases between retinal and a number of aliphatic and aromatic amino-acids were also reduced, and spectral changes observed which were almost identical with those obtained with the reduction of N-retinylidene-opsin and alkaline indicator yellow. At room temperature all these reactions were complete within 10 sec after the addition of sodium borohydride.

Since rhodopsin reacts with sodium borohydride during its bleaching by light to yield a product having the spectrum of a reduced Schiff base, one of the intermediates of bleaching before the hydrolysis to free retinal and opsin must expose the Schiff base linkage. To identify this intermediate, we examined the reaction of sodium borohydride with metarhodopsin I and metarhodopsin II.

Irradiation of a rhodopsin solution (Fig. 5, curve 1) in 66 per cent glycerol, pH 6.5, at  $-20^{\circ}\text{C}$  isomerizes the retinaldehyde chromophore to a steady-state mixture of pigments (curve 2): metarhodopsin I (the all-*trans* chromophore), isorhodopsin (9-*cis* chromophore) and rhodopsin (11-*cis* chromophore)<sup>2</sup>. At  $-20^{\circ}\text{C}$  metarhodopsin I is not converted to metarhodopsin II. The spectrum is not significantly altered by the addition of three 0.5-mg portions of sodium borohydride (curves 3, 4 and 5). To show that sodium borohydride could function at  $-20^{\circ}\text{C}$ , the solution was warmed to room temperature for 1 h to allow the metarhodopsin to hydrolyse to free retinal and opsin. (By this time the borohydride previously added had been hydrolysed.) On re-cooling to  $-20^{\circ}\text{C}$ , curve 6 was obtained. It shows the presence of isorhodopsin and rhodopsin, and a peak near 390 m $\mu$  due to retinal. Addition of two portions of sodium borohydride at  $-20^{\circ}\text{C}$  caused the latter band to be replaced by one near 330 m $\mu$  (curves 7 and 8), showing that sodium borohydride can reduce retinal to retinol even at  $-20^{\circ}\text{C}$ . Thus its failure to react with metarhodopsin I at that temperature is significant.

Similar experiments have been performed with metarhodopsin II at  $-20^{\circ}\text{C}$ . The absorption of this pigment, unlike that of metarhodopsin I, does fall slowly when portions of sodium borohydride are added. However, at this temperature it does not react nearly so rapidly with

sodium borohydride as free retinal or the non-protonated Schiff base of alkaline indicator yellow.

The work at  $-20^{\circ}\text{C}$  suggests that metarhodopsin II is more reactive than metarhodopsin I toward sodium borohydride. Fig. 6 shows an experiment at  $2^{\circ}\text{C}$  which demonstrates this point more clearly. Irradiation of a rhodopsin solution at  $2^{\circ}\text{C}$  and pH 6.5 produces an equilibrium mixture of both tautomers (curve 2). When sodium borohydride is added, the metarhodopsin II absorption at 380 m $\mu$  is replaced within seconds by absorption at 330 m $\mu$ , whereas considerable metarhodopsin remains (curve 3). The disappearance of the remaining metarhodopsin I (curves 4 and 5) is associated with further rise in absorption at 330 m $\mu$ , metarhodopsin II apparently being reduced as fast as formed.

It seems clear, therefore, that metarhodopsin II is reduced much more rapidly by sodium borohydride than metarhodopsin I, if the latter is reduced at all. Thus,

Fig. 5. The failure of metarhodopsin I to react with sodium borohydride at  $-20^{\circ}\text{C}$ . Curve 1 is the spectrum of rhodopsin, pH 6.5, in 66 per cent glycerol at  $-20^{\circ}\text{C}$ . Exhaustive irradiation at this temperature produces a steady-state mixture of rhodopsin, isorhodopsin, and metarhodopsin I (curve 2). Curves 3, 4 and 5, each recorded 30 min after successive additions of sodium borohydride, show no significant changes. Apparently sodium borohydride does not react with any of these pigments. To show that it can act as a reducing agent at  $-20^{\circ}\text{C}$ , the solution is warmed to room temperature for an hour to allow the metarhodopsin I present to hydrolyse to free retinal and opsin. It is re-cooled to  $-20^{\circ}\text{C}$  (curve 6); this displays a peak at about 480 m $\mu$  due to isorhodopsin and rhodopsin, and a peak at about 387 m $\mu$  due to free retinal. The addition of two further portions of sodium borohydride causes the latter band to be replaced by the retinol band at about 330 m $\mu$  (curves 7 and 8, each recorded 30 min after adding portions of sodium borohydride).

Fig. 6. The reaction of sodium borohydride with an equilibrium mixture of metarhodopsins I and II. Irradiation of rhodopsin (spectrum 1) at  $2^{\circ}\text{C}$ , pH 6.5, yields an equilibrium mixture of metarhodopsin I ( $\lambda_{\max}$  478 m $\mu$ ) and metarhodopsin II ( $\lambda_{\max}$  380 m $\mu$ ) (spectrum 2). Curve 3, recorded within 30 sec after adding sodium borohydride, shows that metarhodopsin II is wiped out, being replaced by N-retinyl-opsin ( $\lambda_{\max}$  333 m $\mu$ ), while considerable metarhodopsin I remains. On warming the solution, the remaining metarhodopsin I was transformed, presumably over metarhodopsin II, to N-retinyl-opsin (curve 4). On re-irradiating in the warm, the remaining rhodopsin and isorhodopsin were bleached and also reduced to N-retinyl-opsin (curve 5).

when rhodopsin is irradiated in the presence of sodium borohydride, metarhodopsin II is probably the first intermediate to be reduced.

### Discussion

Rhodopsin itself is not attacked by sodium borohydride; reduction of the Schiff base linkage of retinal to opsin occurs only after it is irradiated. Nor does potassium borohydride, used earlier in our laboratory to reduce retinal freed by the bleaching of rhodopsin, attack rhodopsin<sup>18</sup>. These observations are not surprising in the light of earlier work which has shown that attachment to opsin protects retinal from a variety of chemical attacks. Lipoxidase, for example, attacks the polyene chain of retinal after rhodopsin is bleached, but has no effect on rhodopsin itself<sup>19</sup>. Similarly, hydroxylamine, during the bleaching of rhodopsin, traps retinal away from opsin by oxime formation, but does not attack rhodopsin<sup>17</sup>. (It is an interesting sidelight that hydroxylamine does take retinal from the cone pigment, iodopsin<sup>18</sup>.)

There are many lines of evidence that configurational changes in opsin accompany the bleaching of cattle rhodopsin<sup>1</sup>. A large increase in entropy occurs in the transition metarhodopsin I  $\rightarrow$  metarhodopsin II<sup>2</sup>; also, as the result of bleaching, new groups on opsin—two sulphhydryl groups and one acid-binding group—are exposed. Further, the optical rotation at 233 m $\mu$  becomes less negative on irradiation<sup>19</sup>. Sodium borohydride may not be able to effect a reduction until such configurational changes have exposed the Schiff base linkage, apparently at the stage of metarhodopsin II.

If one assumes that metarhodopsin I is a protonated, and metarhodopsin II a non-protonated, Schiff base, a further explanation must be considered. Protonation of the Schiff base linkage may block reduction in the earlier intermediates, whereas loss of this proton in the transition from metarhodopsin I to metarhodopsin II may render the latter molecule more susceptible to reduction. This suggestion implies that sodium borohydride may react selectively with the uncharged rather than with the protonated Schiff base, at least in this instance. There is as yet no clear evidence that such selective reduction of the uncharged species occurs generally. On the contrary, model Schiff bases of retinal and various amino-acids, brought to acid pH so that their  $\lambda_{\max}$  is about 440 m $\mu$ , characteristic of the protonated species, react so rapidly with sodium borohydride at room temperature that we are unable to follow the kinetics. The same is true of the reaction of uncharged Schiff bases, however, so that we cannot conclude definitely what species is attacked.

It should be noted that if in rhodopsin the chromophore is bound as a protonated Schiff base, this linkage has

extraordinary properties. The complete stability of the rhodopsin spectrum between pH 4 and 10 means that the Schiff base retains its proton even at the latter pH, implying that it possesses a  $pK$  much higher than 10. We do not know of any model Schiff base that displays such a high  $pK$ . It is possible alternatively that the protonated linkage may be bound into the protein structure in some way that makes it inaccessible to any reagents, even such as might remove a proton. As already said, the conjugate acid of N-retinylidene-opsin, in which retinal is bound to denatured opsin as a protonated Schiff base at the original site, reacts rapidly with sodium borohydride. This indicates that some aspect of the native opsin structure shields the protonated Schiff base linkage from reaction with sodium borohydride.

In summary, sodium borohydride, though it does not react with rhodopsin, reduces an intermediate—apparently metarhodopsin II—in the bleaching of rhodopsin by light. The special vulnerability of metarhodopsin II is probably due to the exposure of the Schiff base linkage between retinal and opsin through unfolding of the protein, as also possibly to the loss of a proton by this linkage. The reduction of the Schiff base linkage anchors retinal firmly to the chromophoric site in opsin as the stable secondary amine, N-retinyl-opsin. Experiments are in progress to identify the amino-acids at the binding site.

## PROTECTIVE ACTION OF HEPARIN IN EXPERIMENTAL IMMUNE NEPHRITIS

By PROF. B. HALPERN, PROF. P. MILLIEZ, PROF. G. LAGRUE, A. FRAY and J. C. MORARD

Chaire de Médecine Expérimentale du Collège de France et Centre de Recherches sur l'Hypertension artérielle, Hôpital Broussais, Paris

**H**EPARIN has been found to inhibit various forms of tissue damage in hypersensitivity reactions such as the Shwartzman phenomenon<sup>1</sup> and the Arthus lesion<sup>2</sup>. The results reported here provide evidence that heparin exerts a remarkable protective action on allergic nephritis induced in rabbits by injection of heterologous nephrotoxic serum. Following a description of the results, the possible mechanism of action of heparin will be discussed, taking into account the manifold physiological effects of heparin.

The anti-kidney serum was prepared by immunizing ducks with rabbit kidney homogenate incorporated in complete Freund's adjuvants (Difco). The injections were given once a week during 5 weeks. The animals were bled a week after the last injection and the titre of anti-kidney antibody determined by the complement deviation reaction. In spite of identical techniques of immunization, the antibody titre varied considerably from one bird to another. For these experiments only the most potent sera were used.

Fig. 1. Protective action of heparin on kidney damage produced by heterologous anti-kidney serum in rabbits. Mean blood urea nitrogen (upper part) and mean daily proteinuria (lower part) in control group as compared with animals treated with heparin. (The dose of antiserum administered was 8 ml.) Each point represents a mean of values obtained in 4 animals. —, 4 rabbits injected with 8 ml. anti-kidney serum; ---, 4 rabbits injected with 8 ml. anti-kidney serum and heparin.

For the induction of glomerulonephritis, adult rabbits weighing 2.5 kg were used. The animals were previously checked for proteinuria, blood urea nitrogen and blood pressure. The anti-kidney serum was administered by a single intravenous injection of 4 ml. in one series, and of 8 ml. in another one. The animals of both series were subdivided into two groups *A* and *B*.

The animals of group *A* received the anti-kidney serum alone.

The animals of group *B* received, with the anti-kidney serum, intravenous injections of heparin in the following manner: 100 mg per animal simultaneously with the injection of the antiserum and 25 mg twice a day during the following 10 days.

A third group of 10 rabbits (group *C*) received an intravenous injection of 8 ml. of normal duck serum.

The animals were placed in individual cages and checked for urine output, proteinuria, haematuria, blood urea nitrogen and blood pressure (measured with the technique described by Grant). Careful histological investigations of the kidney were performed either on biopsy fragments taken between the 10th and 20th day following treatment, or on necropsy preparations from animals which died spontaneously or which were killed deliberately.

Of 19 animals of group *A* receiving the anti-kidney serum alone, all have presented symptoms of severe glomerulonephritis. Ten animals died spontaneously 8–20 days following injection, with symptoms of severe renal failure: proteinuria, haematuria. The blood urea reached, or even exceeded, 150–300 mg/100 ml. (Fig. 1).

The histological examination confirmed the extent and severity of the kidney lesions. There were signs of a generalized endothelial proliferative glomerulonephritis with thrombosis and necrosis of the glomer-

Fig. 2. Daily modifications of serum complement levels after the administration of anti-kidney serum in the control animals and in animals treated with heparin. Each point represents a mean of values obtained in 4 animals. —, 4 rabbits injected with 8 ml. anti-kidney serum; ---, 4 rabbits injected with 8 ml. anti-kidney serum and heparin.

ular capillaries. It was estimated that 60–90 per cent of the glomeruli were involved. These lesions were associated with proliferation of epithelial cells leading to massive crescent-like formations and flocculo-capsular synechiae. In more advanced stages, about 60 per cent of the glomeruli were fibrotic and a great number were completely obliterated. Interstitial fibrosis, fibrinoid degeneration of the arterioles and tubular engorgement with hyaline casts were commonly noted.

The renal lesions were more severe in the animals which received the higher dose of antiserum.

Of the 17 animals forming group *B*, one died with symptoms of renal failure. Haematuria and proteinuria were occasionally observed in the first few days following the treatment, but afterwards they subsided. The blood urea nitrogen remained normal in all animals, except one (Fig. 2).

The histopathological findings confirmed the remarkable protective action of heparin. In animals killed 4 weeks after treatment, the lesions were limited to about 1–5 per cent of glomeruli, all others being apparently normal. The interstitium was normal as well as the arterioles.

Slight and transient proteinuria occurred in some animals of group *C*, and the histological findings here were unimportant.

Fig. 3. Photomicrograph of kidney sections obtained from rabbits treated with anti-kidney serum. *A*, No treatment with heparin. Rabbits 249 (left) and 757 (right). Massive glomerular lesions with endocapillary proliferation, producing obliteration of the lumen of the capillaries. Epithelial proliferation with formation of crescents and complete fusion of the flocculum with the capsula. Periglomerular inflammatory reaction. *B*, Treated with heparin. Left (rabbit 738), glomeruli essentially normal. Slight endocapillary proliferation. Right (rabbit 735), signs of moderate endocapillary glomerulonephritis. Slight proliferative reaction and early hyalinosis.

The results presented in Fig. 2 indicate that the injection of nephrotoxic serum causes a dramatic and long-lasting fall of the serum complement. The effect was almost maximal within a few hours and it seemed to persist so long as the inflammatory process continued. In the heparin-treated group the initial fall was almost of the same importance, but during the 2-3 following days the complement titre rose rapidly and reached or even exceeded transiently the normal values.

The administration of heparin to animals receiving heterologous anti-kidney serum, in a dose high enough to cause in 100 per cent of the control animals severe renal failure leading to about 50 per cent of mortality, reduced markedly both the biochemical and the histopathological symptoms of the renal damage. In the treated group the mortality was minimal (1 out of 17 animals), the blood urea nitrogen remained unchanged and the histological lesions were considerably reduced. These results are in agreement with previous observations reported by Silfverskiöld<sup>3</sup> and Kleinerman<sup>4</sup>.

To be effective the treatment with heparin should fulfil several conditions: (1) the heparin should be administered before or immediately after the injection of the antiserum; (2) it should be given in high dosage; (3) it should be continued for at least one week following sensitization.

The mechanism of action of heparin in immune nephritis is not yet clear. Two possibilities can be envisaged: (1) Heparin may act by virtue of its anticoagulant properties and thus prevent the thrombo-embolic disorders commonly observed in hypersensitivity reactions. This mechanism has been evoked to explain the protective action of heparin against cortical necrosis in the generalized Schwartzman reaction<sup>1</sup>. This may also be the explanation of the preventive action of heparin in the Arthus lesion, in which vascular damage is pre-eminent.

(2) Heparin may act also by its anticomplementary properties. Immune nephritis may be similar either to the Arthus type lesions or to the immune cytolytic type reaction. In both types of reaction complement is involved. While in the cytolytic type of reaction the role of complement is essential, in the initiation of the cellular

damage, it is still conjectural in the case of the Arthus reaction.

Heparin has been found, in our experiments, to prevent immune haemolysis *in vitro*. Our findings suggest also that complement is not bound or only transiently bound by antigen-antibody complexes *in vivo* in heparin-treated animals. If complement is an essential factor in inducing tissue damage in immune nephritis, this mechanism cannot be overlooked. It may be emphasized here that Lachmann *et al.*<sup>5</sup> have recently shown by immuno-histochemical investigations the presence of *in vivo* bound complement in the glomeruli in human glomerulonephritis of varying aetiology. In all these cases the distribution of complement was similar to that of bound human  $\gamma$ -globulin, suggesting that binding of complement by the antibody may be related to the tissue damage.

Whatever the mechanism of action of heparin may prove to be, its remarkable protective effects on tissue damage in immune experimental nephritis strongly suggest potential and unexplored applications in similar human pathological conditions. Our first clinical results in acute glomerulonephritis support this impression.

The action of heparin on tissue damage in immune nephritis, induced in rabbits by injection of heterologous anti-kidney serum, has been investigated. The results obtained indicate that, when administered early enough and in sufficient doses, heparin exerted a remarkable protective effect. While the serum complement level was markedly and lastingly depressed in the animals receiving anti-kidney serum, the fall was only transient in the heparin-treated group.

Whether the action of heparin on immune nephritis is related to its anticoagulant properties or to its complement inhibiting effects is discussed.

## RELATIONSHIP OF APPEARANCE OF ADENOSINE DIPHOSPHATE, FIBRIN FORMATION AND PLATELET AGGREGATION IN THE HAEMOSTATIC PLUG *IN VIVO*

By MRS. J. MARR, DR. J. J. BARBORIAK and DR. SHIRLEY A. JOHNSON

Research Service, Wood V.A. Hospital, Marquette University School of Medicine, Milwaukee, Wisconsin

MANY investigators in the past few years have shown that adenosine diphosphate (ADP) aggregates platelets *in vitro*. This is an important observation, since both haemostasis and thrombus formation are initiated by platelet aggregation and the red blood cells and platelets of whole blood are possible *in-vivo* sources of this nucleotide. Hellem<sup>1</sup> described a constituent of red blood cells which brought about aggregation of platelets and was later identified by Gaarder *et al.*<sup>2</sup>, using the paper chromatographic method for separation of nucleotides, as ADP. Born<sup>3</sup> also had shown earlier that platelets contained high levels of adenosine triphosphate (ATP) which were degraded to ADP as platelet-rich plasma clotted. He then found that ADP added *in-vitro* to platelet-rich plasma brought about platelet aggregation which was inhibited by ATP, by adenosine monophosphate and by adenosine<sup>4</sup>. Although the aggregation of platelets by thrombin has been known for several decades, recent accounts of haemostasis state that thrombin does not appear in shed blood until after platelet aggregation by ADP was completed, so that it has no part in the initiation

of the haemostatic mechanisms. Using ultrastructural techniques *in vivo*, Johnson *et al.*<sup>5</sup> have recently found fibrin, together with large aggregates of platelets, in haemostatic plugs, 30 sec after transection of mesenteric vessels in guinea-pigs. The relationship between the activation of prothrombin to thrombin and the degradation of ATP to ADP, in haemostatic plug formation as well as in the initiation of thrombosis, is seen to be of critical importance.

Born<sup>6</sup> has recently shown that the formation of white bodies or platelet thrombi in the lumen of injured arteries can best be suppressed by infusion of adenosine or 2-chloroadenosine. Haemostatic plug formation was apparently unaffected, since the bleeding time remained unchanged, when the inhibitors were infused, although the formation of thrombi was diminished. Haslam<sup>7</sup> has prevented the aggregation of washed platelets with thrombin by enzymatic conversion of ADP to ATP using pyruvate kinase and 2-phosphoenolpyruvate. This work shows that, at least in this model, ADP must be present for aggregation with thrombin to occur.

We therefore undertook a parallel investigation to document the degradation of ATP to ADP in blood shed after transection of mesenteric vessels in guinea-pigs, correlating it with the appearance of fibrin and aggregation of platelets. The adenosine nucleotides were separated by thin-layer chromatography and the fibrin was identified by ultrastructural techniques. This is the first time the appearance of ADP in haemorrhage, *in vivo*, has been recorded.

The guinea-pigs were anaesthetized with 'Nembutal', the abdomen was opened and the smallest arteriole entering the gut from the inferior mesenteric artery was transected. Samples of blood were collected from the bleeding end of the vessel at designated intervals into capillary tubes, trichloroacetic acid was drawn in and stirring accomplished by moving an iron filing in the capillary tube with a magnet. After 3 min of stirring the extract was separated by centrifugation at 1,500*g* for 10 min. The resulting protein-free extract was applied in 1-ml. volumes in four applications to the cellulose plates for thin-layer chromatographic separation of adenosine nucleotides according to Randerath<sup>8</sup>.

Coagulation of whole blood brings about degradation of ADP in red blood cells and platelets, so the samples were collected with great caution. A siliconized microscope slide was placed under the loop of the gut and tilted so the blood might drain away easily until a few seconds before the sample was to be taken, when a pool of blood was allowed to accumulate so the capillary tube could be rapidly filled.

A 10 per cent solution of trichloroacetic acid was prepared from the crystalline material purchased from Fisher Laboratory Chemical U.S.P. Adenosine and 5' nucleotides (Kit K-2) were purchased from Pabst Laboratories, Division of Pabst Brewing Company, Milwaukee, Wisconsin. Standard curves were obtained using 39.6 mg crystalline ATP ( $\text{Na}_2\text{H}_2\text{ATP} \cdot 4\text{H}_2\text{O}$ , mol. wt. 623) per litre of 0.02 M phosphate buffer, pH 7, and 30.8 mg crystalline ADP ( $\text{NaH}_2\text{ADP} \cdot 2\text{H}_2\text{O}$ , mol. wt. 485) per litre of the same buffer. These curves were based on average molar absorptivity index ( $A_{259}$ ), at 259*m*, on a Beckman spectrophotometer. The standard solutions were mixed with trichloroacetic acid, and applied in 4 applications of 1 ml. each. MN-Cellulose powder 300, Macherey, Nagel and Co., was purchased from Brinkman Instruments, Inc., 115 Cutter Mill Road, Great Neck, New York.

Cellulose plates were prepared by spreading a paste composed of 15 g of cellulose stirred into 90 ml. of distilled water by a Waring blender for 30–45 sec. The plates were then dried in an oven at 105°C for 10 min. Four applications of either protein-free extract of blood to be tested or standard solutions of adenine nucleotides, of 1 ml. each, were placed on the plates. A solvent composed of *n*-butanol/acetone/acetic acid/5 per cent ammonium hydroxide/water (3.5 : 2.5 : 1.5 : 1.5 : 1) was used to develop the test material according to Randerath<sup>8</sup>. After the nucleotides were visualized under an ultra-violet lamp, the separated areas were collected into phosphate buffer, pH 7, and measured spectrophotometrically.

A detailed description of our ultrastructure techniques has been published<sup>5</sup>. The same experiment was conducted, a small mesenteric vessel transected and fixed *in vivo* by dropping cold collidine-buffered<sup>9</sup> 4 per cent osmium tetroxide on the bleeding vessel. The tissue was then dissected out, fixed, dehydrated and embedded in 'Epon' using equal portions of A and B mixture according to Luft *et al.*<sup>10</sup>. The sections were cut on a Porter-Blum ultramicrotome, stained with uranyl acetate and lead citrate<sup>11</sup> and viewed under a RCA EMU3G electron microscope at 100 kV.

**Adenosine triphosphate degradation to adenosine diphosphate in shed blood.** The results of ATP and ADP assays of blood, shed at successive intervals after transection of small mesenteric arterioles, are shown in Fig. 1. Each point on the graph represents a mean value derived from

Fig. 1. A graph depicting ATP degradation during bleeding from a transected mesenteric vessel. The points are interpolated values from curves drawn from actual determinations in 12 guinea-pigs. On the ordinate ATP and ADP are expressed as  $\mu\text{moles}$  per ml. of whole blood, and on the abscissa the duration of bleeding is expressed in seconds.

12 guinea-pigs. In most cases ADP appeared 2–3 sec after bleeding began and 50 per cent of the ATP had appeared as ADP within 10–15 sec. A plateau of ATP degradation was reached about 60 sec after the vessel was severed.

Evidence to suggest that the only adenosine nucleotide resulting from adenosine triphosphate is adenosine diphosphate. The total of ATP and ADP remains so constant (Table 1) that there appears to be no other adenosine nucleotide formed. No additional spots appeared on the cellulose plates following application of the protein-free extract of whole shed blood even after 1 min of bleeding. The standard solutions of adenosine monophosphate and adenosine were applied to the plates, however, and they migrated to their appropriate places. We found it necessary to collect the separations of adenosine diphosphate at the initial times even if they were not visible on the plates under the ultra-violet light following developing, since some ADP was found in the cellulose even though its quantity was less than that necessary to give visible separations. The ATP + ADP totals, however, always revealed any loss of material. The data in Table 1 represent a typical experiment.

**Comparison of adenosine nucleotides in circulating and shed blood.** Born has frequently suggested that injury to the vessel wall might result in release of adenosine nucleotides responsible for platelet aggregation. Along with the assay of the shed blood from transection of the mesenteric vessels, we have carried out heart punctures

Fig. 2. Platelets (PL) can be seen adhering to collagen (C). This transected mesenteric vessel had been allowed to bleed for 15 sec before *in vivo* fixation with cold collidine-buffered osmium ( $\times c. 10,600$ ).

Table 1. ATP DEGRADATION IN SHED BLOOD IN THE INITIAL STAGES OF HAEMOSTASIS

Time (sec)	ATP $\mu\text{M/ml.}$	ADP $\mu\text{M/ml.}$	Total ATP + ADP $\mu\text{M/ml.}$
3.2	1.052	0.155	1.207
8.4	0.695	0.542	1.237
19.9	0.454	0.762	1.216
32.0	0.359	0.897	1.256

on each guinea-pig to determine the degradation of ATP to ADP in circulating blood. We found ADP in some of the samples secured by heart puncture but not in all. When ADP was detected the amount was subtracted from that measured in shed blood. As can be seen in Table 2, the total ATP + ADP is not significantly different in circulating blood from that found in shed blood. We interpreted this to mean that no detectable amount of ADP was released into shed blood by the cells in the damaged vessel wall.

Table 2. COMPARISON OF ADENOSINE NUCLEOTIDES IN CIRCULATING AND IN SHED BLOOD

	$\mu\text{M per ml. whole blood}$	
	Total ATP and ADP, blood shed at 12 sec	Total ATP and ADP, circulating blood (heart puncture)
1	1.200	1.371
2	1.370	1.497
3	1.380	1.570
4	1.540	1.465
5	1.570	1.532
6	1.410	1.450
7	1.390	1.378
8	1.390	1.475
9	1.445	1.456
Mean	$1.410 \pm 0.032$	$1.466 \pm 0.020$
		$P=0.1$

Whole guinea-pig blood was allowed to clot and ATP degradation was measured. Although this investigation is not yet complete it is apparent that ATP degradation in coagulated blood is radically different from that in shed blood with adenosine monophosphate and perhaps adenosine appearing.

**Ultrastructure of fibrin formation and platelet aggregation after 15 sec bleeding.** (a) A few small platelet aggregates were seen almost immediately after bleeding was initiated. Zucker and Borrelli<sup>12</sup>, using light microscopy, have observed platelet adherence to collagen fibres, while Hovig<sup>13</sup>, using ultrastructural techniques, has shown this phenomenon to be mediated through the formation and release of ADP from platelets. We have also observed the phenomenon of platelet adherence to collagen (Fig. 2). The significance of this type of aggregation is not known, but the foregoing investigators have suggested that collagen aggregation may be important in the initial stages of haemostatic plug formation.

(b) For the first time we have observed fibrin formation in association with red cells rather than with aggregated platelets. Fig. 3 shows fibrin fibres with a periodicity of 230 Å in close proximity to red blood cells. This fibrin, which has been observed in quantity, is not very electron dense and has a feathery appearance.

(c) A newly formed platelet aggregate, judging from the number of granules, both electron opaque and electron lucent, present in most of the platelets and the empty spaces between the aggregated platelets, can be seen in Fig. 4. Two red cells appear in the electron micrograph with fibrin fibres emanating from them into the platelet aggregate. The fibrin fibres are well formed, and the oldest part of the aggregate, judging from the reduced number of granules and the disintegrating platelet membranes, is that nearest the red cells and around the fibrin.

We have reported here that as early as 15 sec after bleeding began, very few platelet aggregates were found, but some formation of fibrin was already present. After 30 sec of haemorrhage many very large platelet aggregates and several easily identifiable fibrin loci<sup>5</sup> were seen. Along with the visualization of the ultrastructure of

Fig. 3. Fibrin fibres (F) can be seen adjacent to red blood cells (RBC). This transected mesenteric vessel had been allowed to bleed for 15 sec before *in vivo* fixation with cold collidine-buffered osmium ( $\times c. 10,600$ ).

Fig. 4. Fibrin fibres (F) in close proximity to red blood cells (RBC) can be seen radiating into the platelet (PL) aggregate. This transected mesenteric vessel had been allowed to bleed for 15 sec before *in vivo* fixation with cold buffered osmium ( $\times c. 6,850$ ).

platelet aggregates we now know how much ADP is present in whole blood at the time the platelets are aggregating and the fibrin is appearing.

Although both thrombin and ADP induce platelet aggregation, little consideration has been given to the possibility of the interaction of these two stimuli. Because small amounts of thrombin could not be detected and no fibrin was observed by light microscopy in the initial stages of haemostatic plug formation, many investigators have concluded that aggregation by ADP took place well before thrombin became available, and that no interrelationship could have existed. Since we have shown that fibrin is present at the time of appearance of ADP, an interrelationship between activation of prothrombin and ATP degradation seems very likely. Haslam's recent report<sup>7</sup> of inhibition of thrombin aggregation of platelets accomplished by removal of traces of ADP certainly bespeaks an association between these two separate mechanisms.

The ADP measured in these experiments probably comes in large measure from the red blood cells. We have no data, however, to indicate that it has left the red cells and diffused into the serum where it would be available to bring about platelet aggregation. When ATP

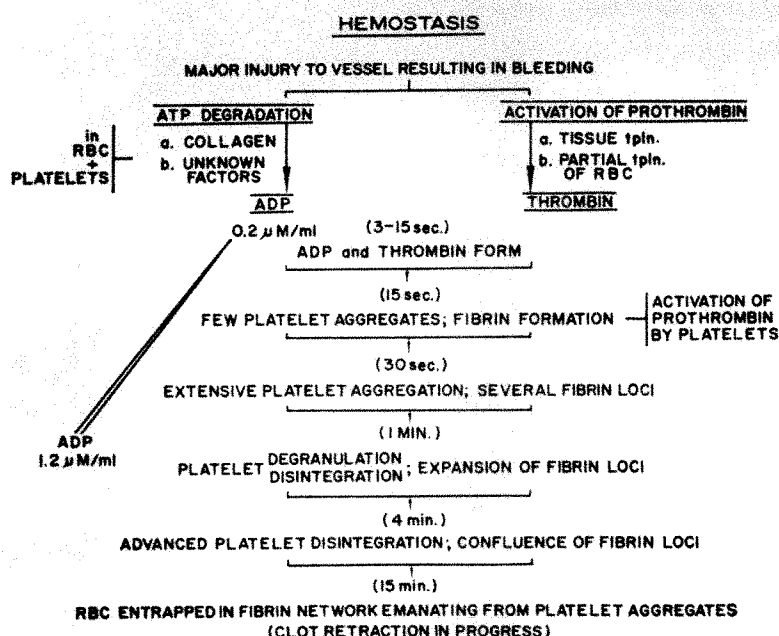

Fig. 5. A schema of the mechanisms of haemostasis after major injury to vessel wall resulting in bleeding

degradation is measured in clotting whole blood, a very complicated pattern emerges, involving formation of adenosine monophosphate and perhaps adenosine after certain critical levels of ADP are reached. The amount of residual coagulation components in shed blood is not known, but the appearance of fibrin does prove that the coagulation mechanisms are initiated.

The stimulus for degradation of ATP in shed blood must certainly come from the damaged vessel wall, even though detectable amounts of adenosine nucleotides are not released into the blood as it passes the injured cells (Table 2). Hellem<sup>1</sup> has stated that ADP release from red blood cells is brought about by contact with a foreign surface. The stimulus may be from the contact with the air, with collagen, or tissue thromboplastin from the injured vessel wall or some as yet undescribed component. The injured vessel wall must change very rapidly, for aggregated platelets building up to form a haemostatic plug must alter the characteristics of the orifice through which the blood is escaping. The con-

centrations of ADP formed in whole shed blood are much higher than those necessary to initiate platelet aggregation in platelet-rich plasma in either rabbit or human material.

The role of red blood cells in the arrest of bleeding should not be disregarded. Since few platelets were seen in our electron micrographs after 15 sec of bleeding and 20 times as many red blood cells are present in circulating blood as platelets, the ADP we measured probably comes in large part from the red blood cells. The close proximity of fibrin to red blood cells suggests that the partial thromboplastin of red blood cells described as thromboplastic cell component by Shinowara<sup>14</sup> may account for the activation of prothrombin to thrombin, thus converting fibrinogen to fibrin.

Fig. 5 summarizes our data on haemostatic plug formation when major injury to a vessel wall resulting in bleeding has occurred.

This work was supported in part by U.S. Public Health Services grant HE-06033-04.

These results show that thrombin and ADP form a few seconds after blood is shed, and both are available to bring about platelet aggregation before the necessary platelets are available. Our schema of the mechanisms

of haemostasis (Fig. 5) attempts to incorporate both activation of prothrombin and degradation of ATP. The interrelation of these two mechanisms remains to be elucidated.

## PROTECTION OFFERED TO POLIOVIRUS-INFECTED TISSUE-CULTURE CELLS BY METHOXY- AND HYDROXY-METHYL COMPOUNDS RELATED TO 2-BENZYL-BENZIMIDAZOLE

By DR. D. G. O'SULLIVAN, DANICA PANTIC and A. K. WALLIS

Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London, W.1

THE high degree of protection conferred by 1-alkyl-2-( $\alpha$ -hydroxybenzyl)-benzimidazoles (I;  $R$  = alkyl,  $R'$  = H,  $R''$  = OH) (ref. 1) on rabbit-embryo kidney cells, infected with types 1, 2 and 3 poliovirus, makes derivatives with modified alkyl substituents at position 1 of particular interest. We have found 1-( $\beta$ -methoxyethyl)-2-( $\alpha$ -hydroxybenzyl)-benzimidazole (I;  $R$  =  $-\text{CH}_2\text{CH}_2\text{OMe}$ ,  $R' = \text{H}$ ,  $R'' = \text{OH}$ ) (ref. 2) (m.p.  $135^\circ\text{--}136^\circ$ ) to be less toxic than the simple 1-alkyl derivatives towards rabbit-embryo kidney cells, the maximum tolerated concentration of the ether being  $300 \mu\text{moles/l.} (\mu\text{M})$ .

This compound, at  $150 \mu\text{M}$  concentration, affords rabbit-embryo kidney cells considerable protection against the cytopathic consequences of infection with types 1, 2

Times are quoted to the nearest quarter of a day.

Approximate initial virus concentration (before dilution): 10<sup>7.2</sup> TCD<sub>50</sub> units per ml. (types 1 and 2 virus) and 10<sup>7.4</sup> TCD<sub>50</sub> units per ml. (type 3 virus).

\* Infected control containing no protective agent. Uninfected and untreated controls always survived more than 5 days. Examination of culture tubes was usually stopped on the fifth day.

M.T.C., maximum tolerated concentration.

and 3 poliovirus. The length and shape of the  $\beta$ -methoxyethyl- are similar to those of the butyl-substituent. Table 1 shows that the protection given by the 1- $\beta$ -methoxyethyl derivative (I;  $R = -CH_2CH_2OMe$ ,  $R' = H$ ,  $R'' = OH$ ) lies between that given by the 1-butyl (ref. 1) and 1-pentyl (ref. 3) derivatives (all tested in tissue-culture by the method previously outlined<sup>1,4</sup>).

An attempt to prepare 1-( $\beta$ -hydroxyethyl)-2-( $\alpha$ -hydroxybenzyl)-benzimidazole by demethylation of the 1- $\beta$ -methoxyethyl compound gave instead the cyclic ether (II) (ref. 2) (m.p. 161°–162°). This ether (maximum tolerated concentration 600  $\mu$ M) is much less toxic to rabbit-embryo kidney cells than other benzimidazoles we have tested and, at 300  $\mu$ M, has selective protective action (activity/toxicity ratio) against the 3 poliovirus types which, although high, is less than that of the 1- $\beta$ -methoxyethyl derivative (Tables 1 and 2). It is slightly less effective than the 1-pentyl compound against the type 2 virus, but more effective than the 1-pentyl compound against the types 1 and 3 viruses. The two ethers, (I;  $R = -CH_2CH_2OMe$ ,  $R' = H$ ,  $R'' = OH$ ) and (II), offer particularly good protection against the cytopathic effects of the types 1 and 2 viruses (Tables 1 and 2). The activity of the cyclic ether (II) makes it necessary to reconsider the role of the  $\alpha$ -hydroxy group.

Table 2. PROTECTION GIVEN BY CYCLIC ETHER (II) AND BY 2-( $\alpha$ -METHOXYBENZYL)-BENZIMIDAZOLE TO CELLS INFECTED WITH TYPES 1, 2 AND 3 POLIOVIRUS

Virus		Mean delay (days) between infection with virus and degeneration of half the cell population			
Type	Conc.	Control	Ether (II) (300 $\mu$ M)	$\alpha$ -Methoxy-HBB (150 $\mu$ M)	HBB (100 $\mu$ M)
1	10 <sup>-1</sup>	1.0	3.5	2.0	2.0
	10 <sup>-2</sup>	1.5	4.75	3.0	3.0
	10 <sup>-3</sup>	2.0	6.75	3.75	3.5
	10 <sup>-4</sup>	0.75	1.5	1.0	1.0
3	10 <sup>-1</sup>	1.0	2.0	1.75	1.5
	10 <sup>-2</sup>	1.75	3.0	2.0	2.0
	10 <sup>-3</sup>		(150 $\mu$ M)*		
2	10 <sup>-1</sup>	1.0	2.0	1.75	2.0
	10 <sup>-2</sup>	1.5	3.0	3.0	3.25
	10 <sup>-3</sup>	2.0	4.5	4.5	5.0

\* Half M.T.C. was used except when the cyclic ether was tested with the type 2 virus. (Strictly the value for HBB itself should be 105  $\mu$ M), but 100  $\mu$ M HBB has been taken as the standard. Untreated-uninfected control cells began to die from over-crowding during the seventh day. Otherwise the footnotes to Table 1 apply.

2-Benzylbenzimidazole (I;  $R = R' = R'' = H$ ) has very low selective activity against type 2 poliovirus, while its  $\alpha$ -hydroxy derivative HBB (I;  $R = R' = H$ ,  $R'' = OH$ ) has high selective activity<sup>5</sup>. Replacement of the  $\alpha$ -hydroxy group by an  $o$ -hydroxy group, similarly sited in space but substituted in the side-chain phenyl group giving structure (III;  $R = OH$ ), slightly reduces the protective activity<sup>6</sup>. In contrast, 2-( $p$ -hydroxybenzyl)-benzimidazole has low activity<sup>6</sup>. We have now examined 2-[ $\alpha$ -(hydroxymethyl)-benzyl]-benzimidazole (I;  $R = R' = H$ ,  $R'' = -CH_2OH$ ) (ref. 2) (m.p. 150°–151°; maximum tolerated concentration 200  $\mu$ M) and find that at 80  $\mu$ M it gives protection to cells infected with type 2 poliovirus similar to that given by 50  $\mu$ M HBB (Table

3). Against the cytopathogenicities of types 1 and 3 poliovirus, the hydroxymethyl compound at 80  $\mu$ M is inferior to 50  $\mu$ M HBB and it provides just detectable protection, of doubtful significance, under the condition of our assays.

Table 3. PROTECTION GIVEN BY 2-[ $\alpha$ -(HYDROXYMETHYL)-BENZYL]-BENZIMIDAZOLE, THE HYDROCHLORIDE OF GLYCERIC ACID (IV) AND HBB TO CELLS INFECTED WITH TYPE 2 POLIOVIRUS

Mean delay (days) before onset of cytopathic effects				
Virus conc.	Control	$\alpha$ -Hydroxymethyl compound (80 $\mu$ M)	Glyceric acid (IV) hydrochloride (60 $\mu$ M)	HBB (50 $\mu$ M)
10 <sup>-1</sup>	1.5	1.75	1.5	1.75
10 <sup>-2</sup>	2.0	2.75	2.25	2.75
10 <sup>-3</sup>	3.0	4.0	3.25	3.75

Initial virus concentration (before dilution)  $\sim 10^{6.8}$  TCD<sub>50</sub> units per ml. Otherwise the footnotes to Table 1 apply.

In order to determine whether an alkyl group at position 1 would increase the activities, as is the case with HBB (ref. 1), 1-ethyl-2-[ $\alpha$ -(hydroxymethyl)-benzyl]-benzimidazole (I;  $R = Et$ ,  $R' = H$ ,  $R'' = -CH_2OH$ ) was prepared by condensing *N*-ethyl-*o*-phenylenediamine with tropic acid by the method described previously<sup>1</sup>. White needles were obtained from aqueous methanol (yield 7 per cent from tropic acid), m.p. 158°–159° (found: C, 77.1; H, 7.0; N, 10.6; C<sub>17</sub>H<sub>18</sub>N<sub>2</sub>O requires C, 76.7; H, 6.8; N, 10.5 per cent). Introduction of the ethyl group results in considerable increase in protective action. At half maximum tolerated concentration, the 1-ethyl derivative (I;  $R = Et$ ,  $R' = H$ ,  $R'' = -CH_2OH$ ) is superior to HBB (100  $\mu$ M) against type 2 poliovirus and is similar to HBB (100  $\mu$ M) against the type 1 and type 3 viruses (Table 4).

Table 4. PROTECTION GIVEN BY 1-ETHYL-2-[ $\alpha$ -(HYDROXYMETHYL)-BENZYL]-BENZIMIDAZOLE TO CELLS INFECTED WITH POLIOVIRUS

Virus		Mean delay (days) before onset of cytopathic effects		
Type	Conc.	Control	1-Ethyl compound 0.5 M.T.C. (100 $\mu$ M)	HEB (100 $\mu$ M)
1	10 <sup>-1</sup>	0.75	1.0	1.0
	10 <sup>-2</sup>	1.0	1.25	1.5
	10 <sup>-3</sup>	1.5	2.0	2.0
3	10 <sup>-1</sup>	0.75	1.25	1.0
	10 <sup>-2</sup>	1.5	1.75	1.75
	10 <sup>-3</sup>	1.75	2.0	2.0
2	10 <sup>-1</sup>	0.75	1.75	1.25
	10 <sup>-2</sup>	1.25	3.25	2.75
	10 <sup>-3</sup>	1.75	4.75	3.75

Initial virus concentrations (before dilution)  $\sim 10^{7.2}$  TCD<sub>50</sub> units per ml. Otherwise footnotes to Table 1 apply.

Each assay (Tables 1 to 4) has been carried out on two separate occasions.

Thus it is not necessary for a hydroxy group to be attached directly to the  $\alpha$ -carbon atom in order to preserve reasonable activity against type 2 poliovirus. The activity of the cyclic ether (II) indicates that an alkoxy group might be as effective (Table 2). 2-( $\alpha$ -Methoxybenzyl)-benzimidazole (I;  $R = R' = H$ ,  $R'' = OMe$ ) (ref. 2) (m.p. 160°–161°) was examined in order to discover the effect of replacing the  $\alpha$ -hydroxy by an  $\alpha$ -methoxy group. It is less toxic to the cells than HBB and shows similar protective action at half maximum tolerated concentration. Table 2 shows that the selective protective action against the type 2 virus is slightly less than that of HBB, while it is slightly more effective than HBB with respect

to the types 1 and 3 viruses. Thus the  $\alpha$ -hydroxy group is not a necessary feature for high activity against the type 2 virus. However, it is just conceivable that some dealkylation might occur in the tissue-culture system. Investigations of other  $\alpha$ -substituted derivatives of 2-benzylbenzimidazole and of their D- and L-isomers are in progress.

(III)

(IV)

2-(*o*-Carboxybenzyl)-benzimidazole (III;  $R = \text{CO}_2\text{H}$ ) was tested because of the activity of the *o*-hydroxy compound<sup>6</sup>. However, at 30  $\mu\text{M}$  (half maximum tolerated concentration) it shows no protective action against the type 1 or type 2 virus and only a small effect, of doubtful significance, against the type 3 virus. Another carboxylic acid (IV) was tested as the hydrochloride at 60  $\mu\text{M}$  (half maximum tolerated concentration) and was found to have no activity with respect to the types 1 and 3 viruses but to offer slight protection against the type 2 virus (Table 3). Mandelic acid at 90  $\mu\text{M}$  (half maximum tolerated concentration) provides no protection against any of the 3 virus types.

2-(*o*-Carboxybenzyl)-benzimidazole (III;  $R = \text{CO}_2\text{H}$ ) was obtained by heating under reflux for 7 h, *o*-phenylenediamine (2.7 g, 0.025 mole) and homophthalic acid (4.5 g, 0.025 mole) in 2M hydrochloric acid (37 ml.). Cooling, filtering and drying the crystals gave a greenish product (5.9 g, yield 94 per cent). The solid, suspended in water, was dissolved in a slight excess of M sodium hydroxide, filtered, and treated with carbon dioxide until no more precipitation occurred. On crystallization from methanol, it gave the *o*-carboxy derivative (III;  $R = \text{CO}_2\text{H}$ ) as white needles, m.p. 320° (dec.) (found: C, 71.2; H, 4.5; N, 10.7;  $\text{C}_{15}\text{H}_{11}\text{N}_3\text{O}_2$  requires C, 71.5; H, 4.8; N, 11.1 per cent).

The glyceric acid derivative (IV) was prepared at the same time as the *bis*-derivative<sup>1</sup> by heating under reflux for 7 h, *N*-methyl-*o*-phenylenediamine<sup>1</sup> (2.44 g, 0.02 mole), tartaric acid (1.5 g, 0.01 mole) and 4M hydrochloric acid (20 ml.). The dihydrochloride of 1,2-*bis*-[2'-(1'-methylbenzimidazolyl)]-ethylene glycol<sup>1</sup> (1.65 g) separated on cooling. On standing the filtrate at 0°, a further crop of crystals (1.4 g) separated. Crystallization from ethanol-

ether after charcoal treatment gave  $\beta$ -[2-(1-methylbenzimidazolyl)]-glyceric acid hydrochloride as white prisms, soluble in saturated sodium bicarbonate, m.p. 212°–213.5° (yield 51 per cent) (found: C, 47.1; H, 5.0; N, 10.1;  $\text{C}_{11}\text{H}_{13}\text{ClN}_2\text{O}_4$  requires C, 47.5; H, 4.8; N, 10.2 per cent).

Table 5 summarizes the approximate relative activities of compounds, all at half maximum tolerated concentration, in protecting rabbit-embryo kidney (ERK) cells against the cytopathic effects of poliovirus type 1 (*L Sc*, 2 ab), type 2 (*P* 712, *Ch*, 2 ab) and type 3 (*Leon* 12 ab) (the virus strains used in this present work). The information is based on our most up-to-date work. Activities are given on an arbitrary scale from  $\alpha$  (very high protection) to  $\epsilon$  (slight protection), as described previously<sup>1</sup>. Until we have completed our investigation of percentage inhibitions of virus growth, Table 5 provides a rough guide to the relative effectiveness of the most interesting compounds we have examined<sup>1,3,4</sup>.

Table 5. APPROXIMATE RELATIVE EFFECTIVENESS IN PROTECTING ERK CELLS INFECTED WITH POLIOVIRUS

Compound	M.T.C. ( $\mu\text{M}$ )	Protective influence*		
		Type 1	Type 2	Type 3
DL-HBB	210	$\epsilon$	$\gamma$	$\epsilon$
D-HBB	210	$\delta$	$\beta$	$\delta$
1-Methyl-HBB†	210	$\delta$	$\beta$	$\delta$
1-Ethyl-HBB†	180	$\gamma(-)$	$\beta$	$\gamma$
1-Propyl-HBB†	80	$\alpha$	$\alpha$	$\beta$
1-Butyl-HBB†	60	$\beta$	$\alpha$	$\gamma$
1-Pentyl-HBB	100	$\gamma$	$\beta$	$\delta$

1- $\beta$ -Methoxyethyl-HBB	300	$\beta$	$\beta$	$\gamma$
1,3-Diethyl-2-( $\alpha$ -hydroxybenzyl)-benzimidazolium iodide	70	$\epsilon$	$\delta$	$\epsilon$
2-( $\alpha$ -(Hydroxymethyl)-benzyl)-benzimidazole	200	0	$\gamma$	0
1-Ethyl-2-( $\alpha$ -(hydroxymethyl)-benzyl)-benzimidazole	200	$\epsilon$	$\gamma$	$\epsilon$
2-( $\alpha$ -Methoxybenzyl)-benzimidazole	300	$\epsilon$	$\gamma$	$\epsilon$
Cyclic ether (II)	600	$\beta$	$\beta$	$\gamma$

\* Ranges are given from  $\alpha$  (very high) to  $\epsilon$  (low); 0 means no activity.

† Same data apply to the DL- and D-isomers.

Experiments on the highly active compounds show that they do not inactivate the virus particles in the absence of cells and that they possess little or no retarding effects on the passage of virus into the cells. Presumably the compounds exert their actions within the cells. The DL- and D-1-propyl-, DL- and D-1-butyl- and DL-1-benzyl-2-( $\alpha$ -hydroxybenzyl)-benzimidazoles are the most effective compounds discovered so far in our investigations<sup>1,3,4</sup>.

## AMINO-ACID COMPOSITION OF HUMAN DERMAL COLLAGEN

By DR. RAUL FLEISCHMAJER\* and PROF. LOUIS FISHMAN

Department of Biochemistry, College of Dentistry, and Department of Dermatology, School of Medicine, New York University

THE amino-acid composition of collagens from various mammalian and other<sup>1</sup> species reveals a uniform pattern characterized by high concentrations of glycine, proline and hydroxyproline, low concentrations of aromatic and sulphur-containing amino-acids, and significant amounts of hydroxylysine. The amino-acid composition of human collagens from bone, tendon<sup>2</sup>, dura mater and uterus<sup>3</sup> has been reported. This investigation

reports the isolation and amino-acid composition of the citrate-soluble, insoluble and urea-extractable collagens from human skin.

Specimens of normal adult skin were obtained from the abdominal wall of fresh autopsy material. The epidermis was removed from the stretched skin by scraping with a scalpel and the skin was lyophilized. The dry weights of the samples ranged from 1.5 to 3 g. They were passed through a micro Wiley mill, resulting in a fine powder which greatly facilitated the subsequent isolation of the collagens. The lipids were removed by extracting<sup>4</sup> with

\* Post-doctoral Fellow of the Arthritis and Rheumatism Foundation; present address: Hahnemann Medical College and Hospital, 230 North Broad Street, Philadelphia 2, Pennsylvania.

20 ml. of ether for 2 h. This operation was repeated twice. After drying, each sample was extracted with 20 ml. of distilled water for 45 min in a Vir-tis homogenizer at 5° C to remove soluble proteins. The water extraction was repeated five times. The last extract contained insignificant amounts of protein as determined by the method of Lowry<sup>4</sup>. The residue was extracted five times with 0.1 M disodium phosphate, pH 8.9, in a manner similar to the water extraction. This step removed other connective tissue proteins, acid and neutral polysaccharides and a small amount of collagen. After washing, the acid-soluble collagen was extracted from the residue by five extractions with 20 ml. of 0.1 M citrate buffer, pH 3.8, in a way similar to that described for the water and phosphate extractions. The combined citrate extracts were dialysed against 0.01 M disodium phosphate and the precipitated acid-soluble collagen was collected by centrifugation, washed with cold water and lyophilized. The residue, after citrate extraction, was washed twice with 0.4 M NaCl, distilled water and lyophilized. This was the insoluble collagen.

Two skin specimens were subjected to an additional extraction. The extraction proceeded as described here up to and including the citrate extraction. After removal of the citrate buffer by dialysis the residue was extracted with 6 M urea for 45 min at 4° C in a Vir-tis homogenizer. The urea-insoluble residue was removed by centrifugation at 15,000 r.p.m. for 30 min, the supernatant was filtered through a fine sintered glass filter, dialysed against distilled water for 3 days to remove the urea, and lyophilized. This was designated urea-soluble collagen.

Reducing hexoses were estimated by the anthrone method without previous hydrolysis<sup>5</sup>. Hexosamines were determined by the method of Boas<sup>6</sup>. Two samples of urea-soluble collagen were examined with wide-angle X-ray diffraction and compared with rat tail tendon collagen. The samples were placed in a micro-beam X-ray with a 100 $\mu$  glass capillary to collimate the X-ray beam. The exposure with nickel-filtered copper radiation at 35 kV and 20 m.amp lasted 10–12 h.

Our insoluble collagen contained elastic tissue. This was removed by autoclaving for 6 h at 25 lb./in.<sup>2</sup> pressure in distilled water. The insoluble elastin and other impurities were removed by high-speed centrifugation and the gelatin supernatant was filtered through a 'Micropore' filter (German Instrument Co.) and lyophilized.

One mg samples of the various collagens were hydrolysed in constant boiling (6 M) HCl for 22 h in evacuated sealed tubes at 110° C. The hydrolysates were dried in vacuum desiccators over NaOH. Amino-acid analyses were performed using a Technicon Autoanalyser which uses the system of Piez and Morris<sup>7</sup>.

Three satisfactory extractions of human skin were used to examine the composition of citrate-soluble and insoluble collagens. Additional samples were extracted with 6 M urea. The insoluble collagen was found to contain 0.2 per cent hexosamine and 0.45 per cent reducing hexose by the anthrone method<sup>5</sup>.

The amino-acid compositions of the citrate-soluble and insoluble collagens of human skin are shown in Table 1. These represent the average of hydrolysates from three different specimens. The analysis shows the characteristic distribution of amino-acids found in collagens from most sources and is not significantly different from human Achilles tendon, dura mater and uterus<sup>2,3</sup>. No corrections were made for destruction of amino-acids during acid hydrolysis.

The investigation of the characteristics and composition of the portion of the insoluble collagen that is made soluble by 6 M urea is in the nature of a preliminary investigation. In each extraction only 4–5 per cent of the initial collagen was dissolved in the 6 M urea. A second extraction yielded no additional material, nor did any subsequent extractions. Following the removal of the urea by dialysis the lyophilized material was quite

Table 1. AMINO-ACID COMPOSITION OF HUMAN SKIN COLLAGENS

Amino-acid	Citrate soluble collagen*	Insoluble collagen*	Urea soluble collagen†	Human Achilles tendon (Eastoe)
Residues/1,000 residues				
Hydroxyproline	84.5	90.9	91.3	92.1

Arginine	47.1	49.0	51.4	49.0

\* Average of hydrolysates from 3 dermis specimens.

† Average of hydrolysates from 2 dermis specimens.

soluble in cold water, indicating that degradation had occurred. However, a single determination of the molecular weight by light scattering gave a value of about 300,000, which is compatible with tropocollagen. X-ray diffraction examinations of the precipitated urea-soluble collagen show patterns consistent with non-oriented collagen. The ring corresponding to the 2.86 Å nodal repeat of collagen was distinct, but a diffuse ring close to the primary beam suggested that part of the collagen molecules may have been packed in fibrous regions.

The urea-soluble collagen contained reducing hexose in amounts equal to skin collagens. The amino-acid composition is shown in Table 1 and represents the average of two skin specimens. The pattern is generally typical of collagen, but glutamic acid, isoleucine, phenylalanine, hydroxylysine and lysine seem to be present in significantly higher concentrations than in the insoluble collagen of human skin from which it was extracted. Further investigation is required before the significance of the urea soluble material can be clarified.

Although no investigator will claim to have isolated homogeneous collagen, a good index of purity is the carbohydrate content. The value of 0.45 per cent reducing hexose found in the insoluble collagen of human skin is in good agreement with the careful investigation of Blumenfeld *et al.*<sup>8</sup> on the reducing hexoses of swim bladder ichthyocoll. Since the glucose and galactose found in their investigation were not polymerized and were linked to the collagen by L-glycosidic bonds, this represents the minimum of hexose in collagen. However, Blumenfeld and Gallop found no hexosamine in ichthyocoll, and this finding was confirmed in our laboratory. The insoluble collagen, however, contained 0.2 per cent hexosamine.

The portion of insoluble collagen that is extracted by 6 M urea is of great interest. There have been reports that urea alters or denatures collagen<sup>9,10</sup>. It is most likely a degraded collagen as indicated by the ready solubility of the lyophilized material in cold distilled water.

No previous reports of the amino-acid composition of urea-extractable collagen have been found. As mentioned earlier, the amino-acid analysis reported here is typical of collagen but contained excesses of glutamic acid, isoleucine, phenylalanine, hydroxylysine and lysine when compared with insoluble skin collagen. These deviations could not be explained on the basis of preferential solution of one of the collagen sub-units since, when compared to the sub-units of rat skin collagen reported by Piez, Eigner and Lewis<sup>11</sup>, the urea-soluble collagen bore no resemblance to the pattern of any sub-unit with respect to the deviant amino-acids. It is hoped that ultra-centrifuge examinations and sub-unit fractionation will clarify the relationship of the urea-soluble material to intact collagen.

This work was supported by a grant to Dr. Milton Levy from the U.S. Public Health Service, RG-4902.

We thank Dr. Bernard N. Bachra for the X-ray diffraction examinations.

## ALPHA-KERATIN

### Molecular and Fine Structure of $\alpha$ -Keratin (IV)

THE elusive nature of the structure of  $\alpha$ -keratin has recently become the subject of renewed speculations stimulated by the impact of electron microscope evidence<sup>1-3</sup>. It is therefore relevant to repeat our earlier warning<sup>2</sup> that the much favoured concept of a '9+2' arrangement of the aggregates of  $\alpha$ -helices within the microfibrils\* was advanced, following interpretation of image details of dimensions comparable with the resolving power of the electron microscope, in terms of the theory of image formation applicable to extended objects.

Consequently, until the analysis of the high-resolution electron microscope images of transverse sections of mammalian hairs and quills has been successfully completed<sup>4,5</sup>, it would not be prudent to insist on the correctness of the foregoing model (which falls also on other grounds<sup>2,6</sup>), let alone to express views about the measure of agreement between the electron microscope and X-ray evidence<sup>7</sup>; for there appears to be equally strong divergence of opinion about what should be considered as the theory applicable to the case of equatorial scattering of X-rays by a system of the aggregates of long chain molecules<sup>7-11</sup>. It is, therefore, reassuring that more recent publications give exclusive attention to this latter problem<sup>10,11</sup>, thus acknowledging the complexity of electron microscope evidence.

We would like to recall that only in what are essentially under-focused conditions, using as a criterion Fresnel diffraction at the edge of the section, do the electron microscope images of microfibrils show a peripheral ring of a variable number of intensity maxima surrounding a central region of one or more intensity maxima<sup>2</sup>. This type of ultrafine structure has been observed in the images of transverse sections of keratin from many sources (porcupine quill, Lincoln, Cotswold and Australian Merino wools and human hair) after treatment with solutions of reducing reagents, followed by specific or non-specific reactions involving metal compounds<sup>12-14</sup>.

It should, of course, be quite clear (and has been amply substantiated by the results of our preliminary tilting experiments<sup>4</sup>) that the high-resolution image of a microfibril in metal-treated keratin cannot be regarded as a simple orthogonal projection from specimen plane to image plane<sup>2</sup>. However, in view of a singular reluctance to accept the wave-optical approach to the problem of image formation, it seems necessary to repeat the outline of our earlier argument. Thus, single metal atoms or their small aggregates deposited along the loci of  $\alpha$  helices perturb the electron wave to give in the image plane an intensity distribution which is subject to modification after small changes of focus, as a consequence of phase changes between the scattered and the background waves. It was, therefore, not unexpected to find that when the coherence of the illuminating beam was altered, by variation of the semi-angular aperture of the condenser lens, or the distribution of the scattered wave in the image plane affected, by variation of the semi-angular aperture of the

objective lens, changes were observed in the distribution of the intensity maxima in the images of microfibrils<sup>2</sup>, as in the case of small changes of focus<sup>2</sup>.

In view of the adverse effect on the image detail of (i) the electron noise, especially where fast photographic emulsions are involved<sup>15</sup>, and (ii) the contamination under the influence of the electron beam, it should not be surprising that the information available in the images of microfibrils could not be easily interpreted in terms of the ultrastructure of metal-treated keratin. Consequently, the direct solution of the problem must be sought using, *inter alia*, information theory.

Any method used to resolve difficulties of this kind should not rely on an *a priori* assumption of the existence of a unique symmetry in the individual images of microfibrils. Moreover, there should be no ambiguity (pace ref. 1) about the procedure adopted, during repetitive photographic printing, for the mutual angular orientation of the successively superimposed images of microfibrils.

Two useful techniques free from any bias of this kind and applicable to any system with cylindrical symmetry have been developed by Markham, Frey and Hills<sup>16</sup> and can be conveniently adapted to an analysis of the peripheral regions of the microfibrillar images in keratin. Following the first method, the exposure time ( $t$ ) of a highly magnified image (in our case  $\times 10^7$ ) is determined, and  $n$  exposures, each of  $t/n$  duration, are made, successive exposures being taken after rotation of the photographic paper by an angle  $2\pi/n$  about the centre of the image,  $n$  being an integer. If the image has  $m$ -fold symmetry, and  $n=m$  or is an integral fraction of the symmetry order, then  $m$  intensity maxima are observed, instead of the general blur of the original photograph, cf. Figs. 1b and 1a, respectively.

Twelve images selected at random were examined using this method and revealed the symmetries indicated in row (i) of Table 1. Entries in the last column, under the 'number of peripheral intensity maxima— $m$ ', indicate the number of microfibrils with no symmetry or symmetries other than those indicated in the preceding columns. Examples of  $m$ -fold symmetry ( $m=5, 6, 7, 8$  and  $9$ ) are given in Fig. 1b, together with the corresponding unrotated images, Fig. 1a.

In the second method, the enlarged image is rotated about its centre while the system is illuminated by a stroboscopic flash with a variable frequency. Thus, when the latter is  $n$ -times the frequency of rotation of the image

Table 1. FREQUENCY OF IMAGES OF METAL-TREATED MICROFIBRILS OF KERATIN SHOWING: (i)-(iv),  $m$  PERIPHERAL INTENSITY MAXIMA; (v) POLYGONAL CROSS-SECTION

\* It is to be regretted that by proposing a new term 'filament', to replace the well-tried 'microfibril', the systematization of nomenclature for fine structural components of keratin, Mercer *et al.* (*Nature*, **201**, 367, 1964) disregarded the long-established connotation of the former term (for example, *Textile Terms and Definitions*, Textile Institute, 1954, *Filament—A Fibre of Indefinite Length*).

$\theta_c$ , condenser semi-angular aperture;  $\theta_a$ , objective semi-angular aperture.

possessing an inherent  $m$ -fold symmetry, then—as before—for  $n=m$  or  $n$  equal to an integral fraction of such a symmetry order,  $m$  stationary intensity maxima are seen. The same twelve images, row (i) of Table 1, were investigated by the stroboscopic method and the results (see, for example, five images in Fig. 1c) confirmed the symmetries obtained by the first method. The stroboscopic technique was used in all subsequent work, as being the more convenient of the two.

Fig. 1

It was of some importance to attempt a quantitative analysis of the available images of microfibrils. This was carried out using observations from two samples of Lincoln wool fibres, rows (ii) and (iii) of Table 1. If it is assumed that the six orders of peripheral symmetry are equally likely to occur, then the  $\chi^2$  test applied to all microfibrils (data in row (iv)) reveals that these results could have arisen by chance and, therefore, no unique symmetry order could be suggested. Thus it is evident that the ultrafine detail of images of microfibrils is not inherently constant.

We have applied similar tests to six images of microfibrils of porcupine quill-tip, comparing the symmetries derived from images recorded at an arbitrary position of focus (judged as 'best' in a through-focus series) with those from images under-focused by  $\Delta f = -0.2 \mu$ , from the original position. It is evident, from Table 2 (column I), that the symmetry changed in four cases (*b*, *c*, *d* and *e*) but remained unaltered in the other two. When the effect of the coherence of illumination was investigated (that is, the size of condenser aperture varied), images *g* to *l* in Table 2 (column II), the symmetry of only one image remained unchanged. Nine of the twelve images (*m-x*, in Table 2, column III) investigated, after a change of objective aperture, revealed changes in symmetry. In an independent investigation Dobb (ref. 17) and private communications, using the first of the above techniques, has

established that no unique symmetry exists in the images of the microfibrils of metal-treated keratin.

In some instances the shape of the rotated images appeared, at certain values of  $n$ , as a 'straight-sided' polygon. Fifty-six images of microfibrils in the transverse sections of Lincoln wool fibres and porcupine quill were investigated, see row (v) in Table 1. Twenty-seven images showed no particular external shape on rotation. Moreover, out of twenty-nine images which revealed positive results in this respect, fourteen images yielded two different but distinct forms. As a particular example, the microfibril on the extreme right-hand side of Fig. 1c (shown to possess nine-fold symmetry of peripheral maxima) exhibited pentagonal and heptagonal external forms. These latter observations are of some importance since Kassenbeck recently reported that the microfibrils in keratin possess a unique pentagonal cross-section<sup>2</sup>.

The results presented here add considerable weight to our earlier doubt regarding the validity of models for the structure of microfibrils based on the evidence obtained from electron micrographs taken at a random focal position. Moreover, the inconclusive nature of the electron microscope evidence available at present and the only partial success of the quantitative analysis of the X-ray diffraction data, stress the need for broadening the attack on the whole problem following, for example, the lines indicated by Lundgren and Ward<sup>18</sup>. In the forthcoming publication we hope to show that a simple consideration of the dimensions and an idealized packing of the microfibrils (without the refinement of Fraser *et al.*<sup>19</sup>), the densities and mean residue weights of the relevant fractions can lead directly to the evaluation of the possible number of the  $\alpha$ -helices in the microfibrils<sup>6</sup>.

### Ultrafine Structure of $\alpha$ -Keratin

THE equivocal evidence for the structure of the  $\alpha$ -keratin microfibril as revealed in transverse section has been discussed<sup>1,2</sup>, and it is clear that other methods of approach to the important problem of the arrangement of protein molecules within the microfibril must be used together with sectioning techniques. Again, there is little experimental evidence about the length of the individual protein molecules in the microfibrils and their possible mode of longitudinal polymerization. Thus, in this communication we present a technique for dispersing the microfibrils, prior to negative staining, which is proving useful in the examination of lateral and longitudinal arrangement of protein molecules in keratin.

Fractionation methods applied to fibrous keratin give rise to two main fractions<sup>3</sup>. One fraction is rich in sulphur compared with the original fibre, has a molecular weight of 22,000 and exists in buffer solutions as a random coil<sup>4</sup>. The other fraction is low in sulphur compared with the original fibre, may have a molecular weight of 100,000, and can be regenerated as oriented films which give an X-ray diffraction photograph largely of the  $\alpha$  type but with traces of the cross and parallel  $\beta$  configurations<sup>5</sup>. Harrap and Gillespie<sup>6</sup> have examined extensively the fractionation of wool keratin after alkaline reduction and have shown that treatment by sodium thioglycollate at 4° C for 18 h at pH 10.5 extracts a protein enriched in the high sulphur fraction and leaves a fibrous residue enriched in the low sulphur protein. This residue has been shown to give a disoriented X-ray diffraction pattern of the  $\alpha$  type<sup>7</sup>. As high sulphur content proteins have been tentatively identified with the matrix which surrounds the microfibrils, it was thought that this type of extraction might give a relatively clean preparation of microfibrils which, because of the reduction of disulphide bonds, might be induced to break up into smaller units by the application of ultrasonic irradiation.

The technique finally adopted was to reduce Merino 64's wool, which had been purified by washing with ether, alcohol, and distilled water, with 0.1 M thioglycolic acid in 0.1 M disodium hydrogen phosphate adjusted to pH 10.0 or 10.5 with sodium hydroxide. The fibrous residue was then transferred to an intracellular physiological buffer<sup>8</sup> containing potassium, magnesium, chloride, and phosphate ions at pH 7.0, and irradiated with ultrasonics at 15 c/s and 20 W cm<sup>-2</sup> for 5 h. The temperature in the water-cooled cell remained at 12° C throughout the irradiation. The dispersed material was centrifuged at 500g for 5 min, the supernatant liquid discarded, the sediment washed with buffer and recentrifuged and, finally, resuspended in 1 per cent sodium phosphotungstate at pH 5.6 and irradiated with ultrasonics for a further period of about 1 h. Drops of the dispersed material were then placed on 'holey' carbon film on specimen supporting grids and examined in a Siemens Elmiskop I electron microscope after desiccation.

It may be noted that, as in the case of transverse sections<sup>1</sup>, optimum contrast in the specimen is found at a slightly under-focused setting of the objective lens with respect to true focus as defined by the absence of Fresnel diffraction at the edge of a hole. Because of this the structure of the carbon film is out of focus and tends to distort the appearance of the specimen. Fig. 1 shows a typical area of the preparation and it is evident that the microfibrils have been dispersed into long filaments or protofibrils; indeed there was no evidence of intact microfibrils remaining in the preparation. Microdensito-

meter traces with a long slit have been made on the negatively stained filaments and reveal widths between 12 Å and 40 Å; however, a width of approximately 20 Å predominates. In the region indicated by the arrows there are three filaments about 12 Å, 18 Å and 40 Å in width, but their identities are not maintained for any great length. In Fig. 1 and other micrographs, some of the 20 Å wide filaments appear to be composed of still smaller filaments twisted together, but it is not yet possible to say how many of these smaller filaments are present because of the background noise.

Fig. 1. Merino wool reduced, dispersed by ultrasonic irradiation, and stained with phosphotungstic acid ( $\times 275,000$ )

It may be tentatively suggested that the smallest filaments seen here are single protein molecules, and that the predominant 20 Å wide filaments are two- or three-strand ropes. Nevertheless, other arrangements of the molecules cannot be excluded. From these results it is difficult to say whether or not any one arrangement is maintained for a great distance along the microfibril, and there is no indication of a unique structure for the microfibril. Further work is being carried out.

Finally, it should be noted that, in an independent investigation, Dobb<sup>9</sup> has dispersed the microfibrils using a different technique and again finds predominant evidence of 20 Å wide protofibrils.

We thank Dr. J. Sikorski for his advice. This work was supported by the Wool Textile Research Council.

## LETTERS TO THE EDITOR

## GEOPHYSICS

## Magnetic Variation Measurements in Iceland

IN certain parts of the Earth, notably Japan<sup>1</sup>, Germany<sup>2,3</sup> and near Alert and Mould Bay in arctic Canada<sup>4</sup>, the pattern of time-variations in the geomagnetic field exhibits considerable local irregularities. These have been attributed to the effects of electric currents induced in highly conducting portions of the Earth, and the suggestion has been made that this high conductivity is evidence of anomalously high temperatures beneath the regions concerned.

There are differences in the pattern of magnetic behaviour between the locations mentioned, presumably because of differences in the geometrical distribution of conducting material. Thus, in Germany and at Alert, the vertical component of magnetic bay-type disturbances changes sign between stations 100 or 200 km apart, while at Mould Bay the vertical component for a range of periods is highly attenuated over a considerable area.

There is no direct proof that temperature, rather than composition or other parameter, is responsible for the increased electrical conductivity. It therefore appeared desirable to examine the pattern of magnetic variation across a region where high temperatures in the crust and upper mantle were to be expected. Iceland, which lies on the Mid-Atlantic Ridge, provides such a region. The central zone of the Island (Fig. 1) includes virtually all the post-Pleistocene volcanic activity as well as the highest-temperature hot springs. This zone is in line with the central rift of the Mid-Atlantic Ridge, along which high heat flow has been measured farther south.

We have recently operated, for a period of several days, recording three-component magnetometers at three stations, shown on the map. Records are also available, for the same period, from the University of Iceland

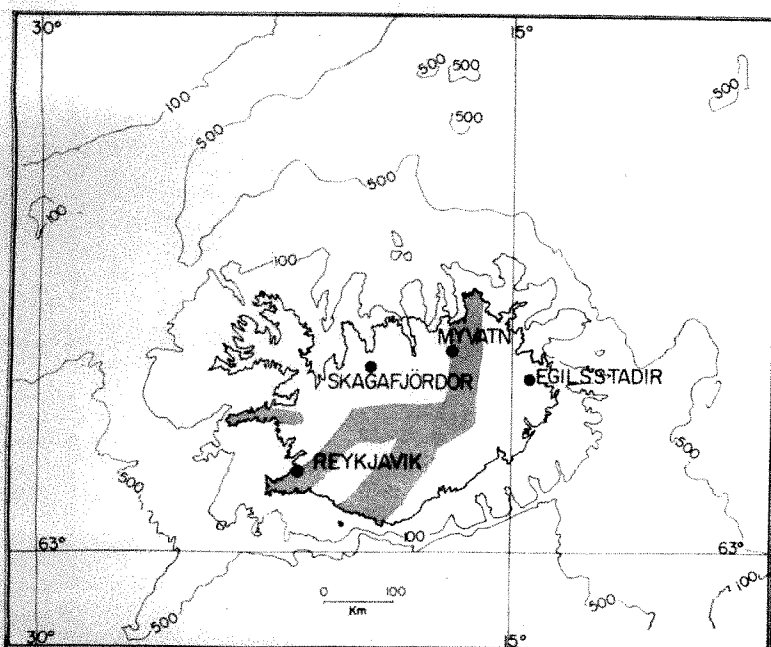

Fig. 1. The shading indicates areas of post-Pleistocene volcanic activity. Depth contours are in fathoms

Fig. 2

magnetic observatory at Reykjavik. Of the temporary stations, Myvatn is on the central zone, while Skagafjörður and Egilsstaðir are located on Tertiary basalts, respectively west and east of the zone. The distance between the latter two is 225 km; this is at least as great as the distance across which reversals in the sign of the vertical component were found in Germany and at Alert.

Records for two components, Z and H, for a portion of a moderately disturbed day are shown in Fig. 2. Considering that Iceland is located in the auroral zone, the coherence between the stations, particularly in H, is remarkably high. No reversals in Z are observed. There is, however, definite attenuation of certain periods in Z, not at Myvatn, but at Egilsstaðir. A preliminary examination of all records suggests that this attenuation is greatest for periods lying between 300 and 900 sec. Comparison with theoretical power spectra for different models<sup>5</sup> suggests that a horizontal layer of high conductivity near the base of the crust could be responsible.

The puzzling feature is the fact that the anomalous effect is not associated with station Myvatn. It will require further observations to confirm and outline the

area of high conductivity, but one possibility is suggested by the submarine contours on Fig. 1. The axis of the Mid-Atlantic Ridge, which enters Iceland from the south-west, is not well defined north of the Island. At depth, the axis of thermal or magmatic activity may continue easterly beneath Egilsstadir, then trend northerly beyond the north-east corner of Fig. 1, toward Jan Mayen Island. On this interpretation, the north-south line of recent volcanic activity which passes through Myvatn owes its location to tectonic control in the crust. Near-surface, linear bodies of hot rock near Myvatn may distort the electromagnetic field, but only at periods too short to be detected on these records.

It is well known that magnetic variation measurements on oceanic islands are affected by the boundary of the highly conducting sea-water. To minimize this influence, the three stations were chosen to be approximately equal distances from the coast. The possibility remains that the different orientation of the coastline nearest to the different stations is responsible for the anomalous behaviour of the vertical component at Egilsstadir. However, the azimuth of the horizontal disturbance vector has been examined for different events, and the phenomenon appears to be independent of it. This would support the suggestion that internal conductivity differences rather than the coastline are chiefly responsible.

More detailed examination of the records, including spectral analysis, is in process, and plans are being made to extend the observations. The work was supported by the National Research Council of Canada, and was carried out with the assistance of the staff and students of the Department of Physics, University of Iceland, and geophysicists of the State Electrical Authority of Iceland.

## RADIOPHYSICS

### Polarization of Jovian Emission at Decametre Wave-lengths

DURING the period September 1–December 31, 1963, observations of the polarization of radio-wave emission from Jupiter were made at 15.2, 16.2, 18.2, 22.2, and 24.2 Mc/s. The Southwest Research Institute two-helix polarimeter<sup>1</sup>, utilizing a twin channel receiver, was expanded so that determination of the cross-correlation of the right and left circular components, in addition to the two opposite circular components, was made separately for each Jupiter burst. This type of radio polarimeter scheme has been described by Cohen<sup>2</sup>. The calibrated polarimeter thus provided determination of the polarization fraction ( $m$ ), axial ratio ( $r$ ) and sense of the Jupiter bursts observed.

One of the predictions regarding the decametre polarization made by Ellis and McCulloch<sup>3</sup>, assuming a cyclotron radiation mechanism, may be stated as follows:

$$\Sigma|r| \propto N^x, \quad x = 1.05$$

Fig. 1. Jupiter burst axial ratio data obtained during September–December, 1963.

where  $N$  = number of Jupiter bursts,  $\Sigma|r|$  = sum of the  $r$ 's for the corresponding  $N$  bursts taken without regard to the sign of  $r$ .

The points shown in Fig. 1 were obtained by calculating  $r$  and the corresponding System III<sub>(1957-0)</sub> longitudes for the best Jupiter bursts observed. The bursts were divided into six 60° longitude ranges and  $\Sigma|r|$  and  $N$  obtained in each range for the left-hand and right-hand bursts separately. The results are plotted in Fig. 1 for the 16, 18, 22, 24 Mc/s frequencies. The solid line has been drawn through the points arbitrarily with the slope 1.05. A summary of the  $x$  value, and the total number of left- and right-hand bursts obtained for each frequency are given in Table 1.

Table 1. VALUES OF  $x$ , ASSUMING  $\Sigma|r| \propto N^x$ , AND POLARIZATION SENSE DISTRIBUTION FOR EACH FREQUENCY

$F$ (Mc/s)	$x$	Per cent deviation	Total number of bursts		RL
			RH	LH	
24	1.14	10.5	40	0	0
22	1.08	2.8	412	10	2
18	0.916	-12.4	386	7	1
16	1.01	-3.8	267	56	0
Totals	—	—	1,105	73	3

The deviation from the predicted slope is within  $\pm 13$  per cent for all frequencies reported and is roughly equal to the experimental error for  $|r|$ . This agreement is similar to that reported by Dowden<sup>4</sup> for polarization measurements at 10.1 Mc/s. It should be noted that for the September observations  $m$  was assumed to be unity (as was also assumed by Dowden), while the  $r$  data for October–December include the effects of the  $m$  determination. No distinction has been made in the data reported here because there is no apparent effect on the results.

The results indicate consistent values of burst axial ratios independent of System III longitude. This and the observed dependence of  $\Sigma|r|$  on  $N$  are both consonant with the cyclotron source model within experimental error. It should be noted, however, that differing

average values of  $r$  associated with the three primary sources have been obtained by Carr *et al.*<sup>5</sup> and from the data obtained in 1962 with the earlier two-helix polarimeter<sup>1</sup>. The question of  $r$  versus longitude remains to be settled by a greater quantity of precise  $r$  determinations.

## PHYSICS

### Measurements of Cavity Loss in a Pulsed Ruby Laser

In a cavity laser system, oscillation by stimulated emission occurs when the gain is sufficient to overcome the total loss in the cavity. Cavity loss not only determines the threshold condition of laser emission, it is also related to various properties of the laser output, such as the mode structure and the mode pulling effects. It is therefore important to measure accurately the cavity loss in a laser system. Previous workers have used the threshold electric input energy of the xenon flashtube as a means of evaluating the cavity loss for a pulsed ruby laser<sup>1-3</sup>. The non-linear behaviour of the xenon flashtube can cause measurement error, especially when the measurement was made over a wide range of temperature. There are two parts to this non-linear property: the total and peak radiant outputs in the pumping band are not linearly proportional to the electric input to the flashtube<sup>4</sup>, and the dependence on time of the radiant output varies with the electric input. However, if the time-varying flashtube radiant output power in the pumping band of the laser is directly measured, the total threshold radiant energy can be obtained by time integration of this pumping power up to the onset of the laser emission, assuming that the fluorescence decay time is long. This results in a loss measurement independent of the non-linearity of the flashtube.

For a pulsed ruby laser, we may assume a four-level system<sup>5</sup> to include both the  $\bar{E}^2(E)$  and  $2\bar{A}^2(E)$  metastable levels. The other upper states besides the broad pumping band are neglected in this analysis<sup>5</sup>. The rate equation for the ground state population density is

$$\frac{dn_1}{dt} = -P(t,e)n_1 + (n_2 + n_3)\frac{1}{\tau} \quad (1)$$

where  $n_1$ ,  $n_2$ , and  $n_3$  are the population density of the ground-state, the  $\bar{E}^2(E)$  and the  $2\bar{A}^2(E)$  levels, respectively,  $\tau$  is the fluorescence decay time of the metastable levels, and  $P(t,e)$  is the probability of excitation within the entire pumping band in per atom per sec. It depends on the electrical input  $e$  to the flashtube and is a function which varies with time.

In the measurement procedure, the pumping input was maintained at a sufficiently high level such that the laser threshold condition was reached within 200  $\mu$ sec from the beginning of the pumping. Since  $\tau$  is 3.2 msec<sup>6</sup>, the second term on the right-hand side of equation (1) may be neglected. We then obtain, at threshold:

$$n_1 = n_0 e^{-E_T} \quad (2)$$

where  $n_0 = n_1 + n_2 + n_3$  and  $E_T = \int_0^{t_0} P(t,e)dt$ .  $t_0$  is the time at the onset of the laser emission since pumping started at  $t=0$ .  $E_T$  is therefore proportional to the total threshold radiant pumping input energy which is a function of the temperature  $T$  for a given laser.

We further assume that the two metastable states, separated by 29 cm<sup>-1</sup>, are in thermal equilibrium and are related to each other by:

$$n_3/n_2 = e^{-42/T} \quad (3)$$

The normalized population inversion is then given by:

$$\delta = \frac{1}{n_0} \left[ n_2 - \frac{g_2}{g_1} n_1 \right] = \frac{1}{(1 + e^{-42/T})} - \frac{n_1}{n_0} \left[ \frac{1}{(1 + e^{-42/T})} + \frac{g_2}{g_1} \right] \quad (4)$$

where  $g_1 = 4$  and  $g_2 = 2$  are the statistical weights of the ground state and the  $\bar{E}^2(E)$  level, respectively.  $\delta$  is related to  $\alpha$ , the gain per unit length along the amplifying medium, by<sup>4</sup>:

$$\delta = \frac{g_2}{g_1} \frac{\Delta\nu_T}{(\Delta\nu_r \cdot \alpha_r)} \cdot \alpha \quad (5)$$

where  $\Delta\nu_T$  and  $\Delta\nu_r$  are the  $R_1$  line-width at temperature  $T$  and at room temperature, respectively, and  $\alpha_r$  is the absorption coefficient in cm<sup>-1</sup> at room temperature.  $\alpha$  multiplied by the length of the rod must be equal to the loss per pass of the laser cavity at threshold.

Combining equations (2), (4), and (5), we obtain:

$$\frac{E_T}{E_R} = \frac{\ln \left[ 1 - \frac{g_2}{g_1} \frac{\Delta\nu_T \alpha}{(\Delta\nu_r \alpha_r)} (1 + e^{-42/T}) \right] - \ln \left[ 1 + \frac{g_2}{g_1} (1 + e^{-42/T}) \right]}{\ln \left[ 1 - \frac{g_2}{g_1} \frac{\alpha}{\alpha_r} (1 + e^{-42/T}) \right] - \ln \left[ 1 + \frac{g_2}{g_1} (1 + e^{-42/T}) \right]} \quad (6)$$

where  $E_R$  is the value of  $E_T$  at room temperature. Using the temperature dependence of  $R_1$  line-width measured by Aagard<sup>7</sup> and by McCumber and Sturge<sup>8</sup>, and also taking<sup>4</sup>  $\alpha_r = 0.272$  cm<sup>-1</sup>,  $E_R/E_T$  was calculated as a function of  $\Delta\nu_T$  for  $\alpha = 0, 0.10, 0.135$ , and  $0.2$ . The results are plotted in Fig. 1.

Cavity loss measurement was performed on a 1.25 in. long sapphire-clad ruby rod with a 0.080-in. diameter ruby core of 0° orientation and of 0.05 per cent Cr<sup>3+</sup> concentration. This rod was purchased from Linde Company in 1962. The ends are coated with 89 per cent reflectivity aluminium mirrors. An F/T-524 flashtube was used for the pump. Two photomultipliers were used. One monitored the flashtube output after passing through a green filter with a pass band similar to the green absorption band of the ruby. The output was proportional to  $P(t,e)$ . The other photomultiplier monitored the laser output, thereby yielding the value of  $t_0$ . The time integration of the output of the first photomultiplier up to  $t_0$

Fig. 1. Normalized threshold pumping input energy  $E_T/E_R$  as a function of  $R_1$  line-width, for four different values of loss per cm  $\alpha$ . The circles are the experimental data measured on a 1.25 in. sapphire-clad ruby rod.

then yielded a quantity proportional to  $E_T$ . Since only the value of  $E_T$  normalized to that at room temperature was required, the proportionality constant was cancelled out. The measurement was carried out in the range from 77° K to 293° K and the results plotted in Fig. 1. The agreement between the experimental data and the theoretical calculation for  $\alpha = 0.135$  is nearly perfect.

This yields a total cavity loss of 43 per cent per pass in the ruby rod studied. The end reflectivity loss contributes 11 per cent per pass. Assuming the diffraction loss and other end losses of 25 per cent, the scattering loss is 7 per cent per pass. These results are very comparable to those measured at reduced temperature on other Linde ruby laser rods grown during the same period of time<sup>2</sup>.

The method described here eliminates the inaccuracy and difficulty due to the non-linear property of flashtube in the conventional laser cavity loss measurements. Since measurements are made at relatively high pumping input, there is no need to search tediously for the threshold pumping energy. The measurement results obtained indicate that the cavity loss is essentially constant over the temperature-range investigated, and the assumed four-level system is an adequate description for the pulsed ruby laser.

I thank R. L. Aagard and J. F. Ready for their advice, and G. N. Otto for making the experimental measurements.

### Three-body Ionic Recombination

THOMSON'S theory<sup>1</sup> of three-body recombination of positive and negative ions:

invokes the artifice of a fictitious trapping distance such that recombination may be supposed to occur if either ion collides with a neutral molecule when within this distance from the other. In recent years the theory has been elaborated by several investigators<sup>2</sup> and the predictions regarding the recombination coefficient have consequently been considerably modified. However, the basic artifice is retained though it does not form an altogether satisfactory foundation on which to build a precise theory. We here outline an entirely different approach exploiting the fact that a quasi-equilibrium is quickly established in which the rate at which bound ion-pairs are formed and destroyed is very much greater than the rate at which their number density changes<sup>3</sup>. In so far as the contribution from charge transfer is merely additive, our approach is effectively exact in the region where the three-body recombination coefficient  $\alpha$  is directly proportional to the number density,  $N(M)$ , of neutral atoms.

Let the number density of ion-pairs having internal energy between  $x$  and  $x+dx$  be  $n(x)dx$  in the quasi-equilibrium state and be  $n_0(x)dx$  in thermodynamic equilibrium. Write:

$$\rho(x) = \frac{n(x)}{n_0(x)}, \quad x < 0 \\ = 1, \quad x > 0 \quad (2)$$

Considering a gas of neutral atoms and ion-pairs of internal energy  $x$  denote the rate coefficient describing those collisions which change the internal energy to between  $y$  and  $y+dy$  by  $K(x,y)dy$ .

In the quasi-equilibrium state we have that:

$$n(x) \int_{-I}^{\infty} K(x,y)dy = \int_{-I}^{\infty} n(y)K(y,x)dy \quad (3)$$

where  $-I$  is the most negative internal energy reached. With the aid of (2) and the principle of detailed balancing it may be shown that (3) is equivalent to:

$$\rho(x) \int_{-I}^{\infty} K(x,y)dy = \int_{-I}^{\infty} \rho(y)K(x,y)dy \quad (4)$$

If  $K(x,y)$  is known (and in any particular case it may be calculated) this integral equation for  $\rho(x)$  may be solved to any desired accuracy. The rate recombination equals the net rate at which ion-pairs flow downwards in  $x$ -space past any fixed level  $-J$  so that:

$$\alpha N(A^+)N(B^-) = N(M) \int_{y=-J}^{\infty} \int_{x=-I}^{\infty} \{n(y)K(y,x) - n(x)K(x,y)\} dx dy \quad (5)$$

where  $N(A^+)$  and  $N(B^-)$  are the number densities indicated. Hence  $\alpha$  may be found.

We have as yet carried out detailed computations only on ions recombining in their parent gas (for which case  $K$  is determined by resonance charge transfer). The preliminary value which we obtained for  $\alpha$  in this special case does not differ appreciably from that given by the original simple formula of Thomson (as corrected by Loeb<sup>1</sup>) and the temperature dependence is the same. A fuller account of the work will be published elsewhere.

## GEOLOGY

### Late Quaternary Terraces on Mount Carmel (Haifa, Israel)

REMNANTS of two marine quaternary terraces, corresponding to a sea-level of 5 m and 15 m above sea-level respectively, have been revealed by boreholes and excavations during housing projects on the N.N.E. piedmont of Mt. Carmel in Haifa, Israel.

The area of approximately two square kilometres, known as the Kyriat Eliahu suburb of Haifa, is covered mainly with alluvial soils and some mountain talus. Numerous middle palaeolithic artefacts<sup>1</sup> which are obviously *non in situ* have been found scattered over the surface. In several places the bore holes and excavations encountered marine calcareous sandstone, resting on a platform cut in the mountain formations (dolomite and marly chalk of Cenomanian age) (Fig. 1).

The younger (lower) terrace has been traced on a stretch of 1.5 km up to the present shore (Fig. 2). A conglomerate, 0.5 m thick, cemented by calcareous sandstone and typical of beach environment, was found resting on a chalky bedrock at 4 m, thus determining the level of the terrace-forming sea as approximately 5 m above the present sea. The calcareous sandstone is light in colour, is virtually unweathered and is mainly of an oolitic type<sup>2</sup>. Its maximum thickness known so far is 1 m. The calcareous sandstone is

Fig. 1

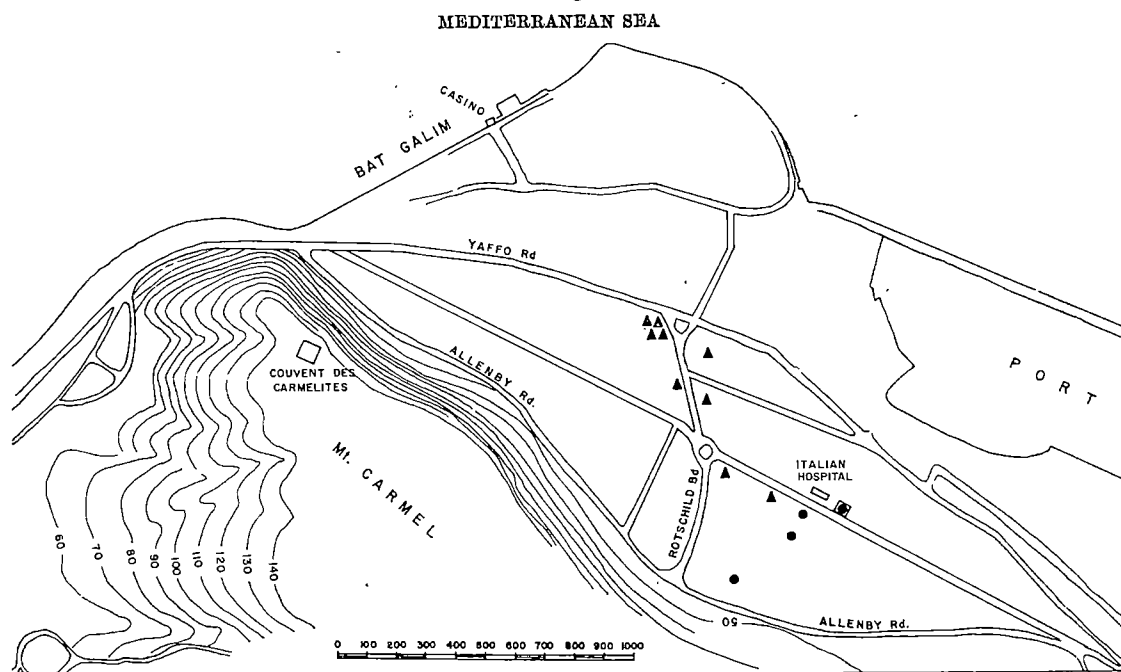

Fig. 2. ●, Upper terrace; ▲, lower terrace

covered by a black plastic clay of swampy character containing flint pebbles.

The marine layer of the upper (older) terrace is up to now known only in three localities, an excavation and two boreholes. This is a coarse, reddish, very fossiliferous calcareous sandstone, not oolitic, passing downwards and upwards to a strongly recrystallized hard coquina. Only *Loripes lacteus* in enormous quantities has been determined until now with certainty, together with some *Miliolidae* and *Streblus* spp.

The patchy character of the layer shows itself clearly in a large recent excavation. Its thickness varies there from 0 to 1 m. The discontinuity of the layer and the red colour of the sand and clayey sand overlying it point to a strong and prolonged weathering. The calcareous sandstone rests directly on the bed-rock, which is dolomitic in one of the localities and chalky in others, or on a sporadically distributed conglomerate, 20 cm thick, cemented partially by calcareous sandstone. The marine layer is covered by red-brown clayey sands containing flint pebbles and gradually passing upwards to a dark grey clay. The level of the marine sandstone in a borehole near the mountain is at 14 m, thus giving 15–16 m as a most probable level of the terrace-forming sea.

On general geological and petrographical considerations the younger terrace is regarded as having been formed by the Late Monastirian sea<sup>1</sup>. The older terrace corresponds, according to its level and by comparison with the Lebanon coast<sup>2</sup>, to the Main Monastirian sea<sup>3</sup>, although no *Strombus bubonius* has as yet been found in it. To our best knowledge only one specimen of *S. bubonius* has been found so far in Israel (several years ago<sup>5</sup> in the vicinity of the area under discussion) and no evidence exists that it was *in situ*.

We thank the Soil Mechanics Laboratory of the Technion, Haifa, which kindly provided the samples and data from the boreholes.

Fig. 1. Concurrent changes in electrical conductance, pH, chlorophyll and dissolved oxygen during the successive periods of illumination and darkness

During the following 49-h dark period, pH dropped from 8.03 to 7.93, and oxygen from 0.14 mM/l. to 0.06 mM/l. Chlorophyll content showed decreasing tendency. The conductivity ratio increased by 0.03 per cent.

Park *et al.*<sup>1</sup> explained the change in conductance due to transformation of bicarbonate ion to carbonate ion and vice versa. In our experiment the observed change in the conductance can be explained by the same mechanism; photosynthesis transforms bicarbonate ion to carbonate ion and respiration does the opposite.

When we know more about the electrochemical properties of sea-water, it may be feasible to estimate the magnitude of net photosynthesis and respiration by the measurement of electrolytic conductance.

### Uptake of Chromium(III) by Particles in Sea-water

ATOMIC reactors at Hanford Laboratories, Washington, introduce easily measurable quantities of chromium-51 into the Columbia River. Although in hexavalent form when produced, some of the radioactive chromium is probably reduced to the trivalent state while passing downstream. Chemical species likely to exist are  $\text{CrO}_4^{2-}$ ,  $\text{Cr}^{+3}$  (aq.) and  $\text{Cr}_2\text{O}_3 \cdot n\text{H}_2\text{O}$ . Observations of Osterberg and Cutshall (unpublished) confirm the presence of several species in the river. They found that  $^{51}\text{Cr}$  could

be removed from river water using membrane filters, chelating resins and both cation and anion exchange resins. Membrane filters (0.65 µ pore size) retained about 20 per cent of the  $^{51}\text{Cr}$  from river water collected near Bonneville Dam. Seymour<sup>2</sup> noted earlier that filters with a 0.45 µ pore size removed about 25 per cent of  $^{51}\text{Cr}$  from river water taken near the mouth of the Columbia River. Measurements made during a recent cruise in the lower 210 km of the river showed that the percentage of  $^{51}\text{Cr}$  attached to particles gradually increased downstream<sup>3</sup>.

The presence of  $^{51}\text{Cr}$  off the mouth of the Columbia River appears closely related to the position of the river effluent.  $^{51}\text{Cr}$  was consistently found on membrane filters, with glass fibre prefilters, to 72 km offshore. In April 1962, 32 pc./l. was found 'as particles' at the mouth of the river. This value decreased to 16 pc./l. at 24 km, 2 pc./l. at 104 km, and was not appreciably above background 136 km–264 km from shore<sup>4</sup>. In June 1962, comparable levels of 'particulate'  $^{51}\text{Cr}$  were found out to 40 km. In April 1963,  $^{51}\text{Cr}$  was detected 40 km from the mouth in water with a salinity of 30 parts per thousand (nominally considered to be the Columbia River effluent), then decreased to background 72 km offshore.

Krauskopf<sup>5</sup> used various substances in an attempt to remove  $\text{CrO}_4^{2-}$  from artificial sea-water. Addition of  $\text{MnO}_2 \cdot n\text{H}_2\text{O}$  rapidly removed most of the chromate, whereas  $\text{Fe}_2\text{O}_3 \cdot n\text{H}_2\text{O}$ , 'clay', apatite, and 'plankton' were not effective over exposure periods of two to fourteen days. On the other hand, Yamagata and Iwashima<sup>6</sup> found  $\text{MnO}_2$  to be inefficient (14.5 per cent) in removing chromium (valence state not given) from sea-water. Chromate ions do not appear to be actively adsorbed on most common particles in the sea, but may be subject to scavenging by some hydrocolloids. There is no evidence that marine pelagic organisms naturally contain much chromium. Generally less than 1 p.p.m. has been reported in ashed samples<sup>7</sup>. Thus, the particulate  $^{51}\text{Cr}$  from filtered sea-water off the mouth of the Columbia must have been either scavenged from solution by hydrocolloids, or present in some form other than chromate (that is,  $\text{Cr(III)}$ ).

At the commonly assumed pH value of 8.2 and an oxidation potential of 0.40 V for open ocean water, chromium should exist predominantly as  $\text{Cr(VI)}$  (ref. 8) and should not be associated with particles. However, a small decrease in oxidation potential of pH would favour the formation of hydrous chromic oxide. This should not be possible in well-oxygenated surface water, but might occur in river water mixed with upwelled water, since the latter is very low in oxygen. The pH of surface water along the Oregon coast has been observed to drop to 7.9 as a result of either river run-off or upwelling<sup>2</sup>. Assuming that  $\text{Cr(III)}$  could exist in nearshore, surface waters of the ocean, it was decided to test the physical behaviour of this species in sea-water.

Chromium, as  $^{51}\text{CrCl}_3$ , was added to plain and nutrient-enriched filtered sea-water (pH 8.0) in the amount of 14 µc./100 ml. ( $6 \times 10^{-3}$  µg Cr including carrier). Enrichment consisted of phosphate, nitrate, silicate, trace metals and vitamins.

The appearance of  $^{51}\text{Cr}$  on membrane filters used to determine radionuclides in suspended matter from the ocean off Oregon indicated that absorption might be important. To investigate this possibility, filters (2.5 cm, 0.45 µ pore size) were soaked in plain sea-water containing  $^{51}\text{Cr(III)}$ . After varying periods, the radioactivity on the unrinsed filters was counted. Adsorption was rapid at first. The amount on the filters at 1 h was three times the amount after 10 min, and after 24 h was 23–30 times the amount after 10 min. Filters which soaked for 24 h recovered 33–43 per cent of the total radioactivity.

Filtered sea-water was adjusted to pH values of 6.0, 7.0 and 8.5 and re-filtered at time intervals ranging from 1 min to 24 h. At pH 6.0, 1.7 per cent of the activity was

recovered on filters; at pH 7.0, 4.0 per cent, and at pH 8.0, 1.5 per cent. There was no significant difference in recovery as a function of time.

Glass beads with an average diameter of 0.2 mm were washed successively in 3 N HCl and distilled water and were then exposed to  $^{51}\text{Cr(III)}$  in filtered sea-water for 24 h. The beads were washed into a weighing tube, rinsed with sea-water, and the supernatant removed. A linear correlation of activity recovered with weight of beads (and, therefore, surface area) was observed.

Uptake of  $^{51}\text{Cr(III)}$  by ten species of phytoplankton algae was measured, but no appreciable differences among species were noted. However, small cells appeared to accumulate somewhat more isotope per cell per unit time than did large cells. Experiments used both living cells in the light and in the dark, and dead cells killed either by heat (100° C for 10 min) or by the addition of formaldehyde. In some experiments various amounts of  $^{51}\text{CrCl}_3$  were added. In others, various numbers of cells were used. When variable amounts of isotope were added to aliquots of rich culture (200 cells/ml.) of *Skeletonema costatum*, the percentage adsorbed was inversely related to the quantity added. For example, after 1.5 h 50 per cent of  $110 \times 10^3$  c.p.m. was recovered, while 70 per cent of  $0.1 \times 10^3$  c.p.m. was recovered.

When a constant amount of isotope was added to cultures of *S. costatum* with cell concentrations ranging from 8 to 80/mm<sup>3</sup>, a doubling of cell concentration resulted in a 1.5 to 3-fold increase in isotope accumulation. Above 80 cells/mm<sup>3</sup>, a doubling of cell concentration produced a linear increase of 22 per cent in isotope accumulation. This relationship prevailed up to 320 cells/mm<sup>3</sup>.

In general, uptake was rapid. Equilibrium was always reached within 24 h. Rates of uptake and final equilibrium values were the same for equal cell numbers of living phytoplankton both in the light and in the dark and for cells killed either with heat or by the addition of formaldehyde.

There is no doubt that Cr(III) is actively adsorbed on living and dead particles at all pH values normal for sea-water. The existence of chromium in this state in sea-water is still problematic, since it is not thermodynamically favoured. However, recent evidence (Johnson and Cutshall, unpublished) suggested that Cr (probably III) attached to particles in the Columbia River may remain bound to particles in sea-water. It will be necessary to demonstrate the actual oxidation state of chromium in sea-water. In addition it would be very desirable to establish the rate of uptake of anionic chromium by phytoplankton and other suspended matter.

## CHEMISTRY

### ( $\text{Re}_3\text{Br}_{11}$ )<sup>2-</sup> Anion in $\text{Cs}_2\text{Re}_3\text{Br}_{11}$

THE detailed structure of the ( $\text{Re}_3\text{Br}_{11}$ )<sup>2-</sup> anion, the formation of which was recently reported by Ferguson and Robinson<sup>1</sup>, has been determined by means of X-ray crystal structure analysis of its caesium salt. It shows the same general configuration as the ( $\text{Re}_3\text{Cl}_{11}$ )<sup>2-</sup> ion (ref. 2). De-

Fig. 1. The ( $\text{Re}_3\text{X}_{11}$ )<sup>2-</sup> ion showing (a) atoms in the plane of the rhenium triangle and (b) atoms out of this plane

tailed analysis of bond lengths and angles reveals some interesting differences between the ( $\text{Re}_3\text{Cl}_{12}$ )<sup>3-</sup> ion (refs. 3 and 4) and the two ( $\text{Re}_3\text{X}_{11}$ )<sup>2-</sup> ions, which raise questions as to the nature of the chemical bonds involved. Further, there is an important difference between ( $\text{Re}_3\text{Cl}_{11}$ )<sup>2-</sup> and ( $\text{Re}_3\text{Br}_{11}$ )<sup>2-</sup>.

Crystals of  $\text{Cs}_2\text{Re}_3\text{Br}_{11}$  are small black needles, orthorhombic, with space group *Pnma*. There are four formula units in a unit cell of dimensions  $a=9.53$ ,  $b=16.08$ ,  $c=13.72$  Å. The calculated density is  $5.38 \text{ g cm}^{-3}$ . A trial structure was proposed on the basis of projections of the Patterson function down each crystallographic axis and was confirmed by three-dimensional electron density maps. All atomic co-ordinates, including individual isotropic thermal parameters, have been refined by three-dimensional least squares using 1412 observed reflexions in the levels ( $0 \dots 6kl$ ) for which the *R* index is 0.167.

Like ( $\text{Re}_3\text{Cl}_{11}$ )<sup>2-</sup>, the ( $\text{Re}_3\text{Br}_{11}$ )<sup>2-</sup> ion has the ( $\text{Re}_3\text{Cl}_{12}$ )<sup>3-</sup> general configuration but with one terminal bromine atom missing from the plane of the rhenium triangle (see Fig. 1). It possesses a crystallographic mirror plane which passes through Re(2) and its two attached terminal bromine atoms (2) and (2'), and also through the bromine atom which bridges Re(1) and Re(1'). In fact it possesses symmetry  $C_{2v}$  within limits of error. Estimated standard errors for Re—Re and Re—Br bonds are  $\leq 0.01$  Å, and for angles,  $\leq 0.5^\circ$ . All bond distances and some angles are listed in Table 1 together with the corresponding mean dimensions for the ( $\text{Re}_3\text{Cl}_{11}$ )<sup>2-</sup> ion (refs. 2 and 5) which has no crystallographic symmetry. These figures show that differences within the chloro-anion which were of only possible significance have been confirmed by quite significant differences in the bromo-anion. On the other hand, there remains one highly significant difference between the two ( $\text{Re}_3\text{X}_{11}$ )<sup>2-</sup> ions.

The Re—Re lengths in ( $\text{Re}_3\text{X}_{11}$ )<sup>2-</sup> do not change on replacing Cl by Br. Furthermore, the Re—Re bonds involving the halogen-deficient rhenium atom are significantly shorter than the third bond, which has the same

Table 1. BOND LENGTHS AND ANGLES

	( $\text{Re}_3\text{Br}_{11}$ ) <sup>2-</sup>	( $\text{Re}_3\text{Cl}_{11}$ ) <sup>2-</sup>
Re(1)—Re(1')	2.48 Å	2.48 Å
Re(1)—Re(2)	2.43	2.43
Re—X(1)	2.49, 2.46	2.30
Re—X(2)	2.39, 2.37	2.29
Re—X(3)	2.72	2.57
Re—X(bridge)	2.52, 2.55, 2.56	2.35
Re—X(bridge)—Re	59°, 57°	61°
X(1)—Re—X(1')	159°	159°
X(2)—Re—X(2')	134°	153°

length as those in  $(\text{Re}_3\text{Cl}_{12})^{3-}$ . This suggests a difference of bond order among the Re—Re bonds.

On replacement of Cl by Br, there is a reduction of  $19^\circ$  in the angle subtended by the out-of-plane atoms  $X(2)$  and  $X(2)'$  at the deficient Re(2), and the Re—Br(2) bonds themselves are significantly shorter than any other in the bromo-anion. These observations suggest that the Re—Br bonds to the non-deficient Re(1) are under considerable strain which is relieved on removal of one halogen atom by bond bending and also by bond shortening to what is presumably a closer approximation to a true single bond length. The first quantitative treatment of the bonding in these trinuclear anions, given by Cotton and Haas<sup>4</sup>, assumes that four orbitals from each rhenium atom are directed to the corners of a square and that all Re—Re bonds are equivalent. For  $(\text{Re}_3\text{Cl}_{12})^{3-}$ , the only structure then known, the first assumption leads to bonds with the out-of-plane chlorine atoms which are bent by about  $10^\circ$  only. However, relative to this scheme, the bending of these bonds in  $(\text{Re}_3\text{Br}_{11})^{2-}$  is increased markedly to  $23^\circ$ . The observations, first, of a preference for highly bent Re—X bonds and, secondly, of the non-equivalence of Re—Re bonds, do indicate that some modification or extension of the Cotton and Haas scheme is required for  $(\text{Re}_3\text{X}_{11})^{2-}$  ions.

The unit cell dimensions and space group of  $\text{Cs}_2\text{Re}_3\text{Br}_{11}$  were previously attributed by us (see ref. 1) to the compound  $\text{CsRe}_3\text{Br}_{10}$  on the basis of bulk analyses. This was because crystals of more than one composition appear to separate under the conditions of preparation and bulk analyses are therefore misleading. We have since characterized a second crystal form from these preparations. The small, black, roughly spherical crystals are orthorhombic with cell dimensions  $a = 11.1$ ,  $b = 14.6$ ,  $c = 14.6$  Å and probable space group  $Ama2$ . They thus have very similar cell dimensions and the same probable space group as  $\text{Cs}_3\text{Re}_3\text{Cl}_{12}$  and are assumed to be the isostructural  $\text{Cs}_3\text{Re}_3\text{Br}_{12}$ . The existence of this  $(\text{Re}_3\text{Br}_{12})^{3-}$  ion is of interest in view of the very considerable steric repulsions which must exist between bromine atoms.

We thank Dr. J. E. Fergusson and Mr. B. H. Robinson for sample preparation, and for advice. This project was supported financially by the New Zealand Universities Research Committee.

### Distribution of Benzcarbazole Isomers in Petroleum as Evidence for their Biogenic Origin

A RECENT paper<sup>1</sup> has discussed the distribution of different types of nitrogen compounds in the  $200^\circ$ – $500^\circ$  C fraction from petroleum of varying geological age. Carbazoles and benzcarbazoles were found to be predominant nitrogen types in all crudes, accounting for 25–70 per cent of total nitrogen in this boiling range, and as much as 2 per cent by weight of the  $200^\circ$ – $500^\circ$  C fraction. Carbazoles and their higher benz analogues also appear to account for a major part of the nitrogen in the  $500^\circ$  C plus residues from these crudes. Among the benzcarbazoles the 1,2-isomers predominate, the 3,4-benzcarbazoles are

present in minor amounts, and the 2,3-benzcarbazoles are altogether absent. A similar distribution has been noted in catalytically cracked gas oils<sup>2</sup>.

An examination of the possible origin of these important nitrogen compound types is worth while because it might provide indirect evidence on the origin of petroleum itself. The indole nucleus is found in Nature in the amino-acid tryptophan and many of the alkaloids<sup>3,4</sup>, while the hexahydrocarbazole nucleus exists intact in the alkaloids strychnine and aspidospermine. Similarly, as indicated in Fig. 1, certain natural alkaloids appear structurally related to the 1,2-benzcarbazoles, and, in a less direct fashion, to the 3,4-benzcarbazoles. Interestingly, no alkaloids known to the author possess the potential 2,3-benzcarbazole nucleus. It is striking in this connexion that the relative probability of producing a benzcarbazole from the naturally occurring alkaloids (that is, 1,2-benzcarba- most likely, 3,4-benzcarbazoles less likely, and 2,3-benzcarbazoles unlikely) is precisely reflected in the actual occurrence of the various benzcarbazole isomers in petroleum. In the absence of alternative explanations for the relative occurrence of the benzcarbazole isomers in petroleum, this suggests that these petroleum nitrogen compounds were formed from ancient plant deposits. The preference for the angular 1,2- and 3,4-benzcarbazole structures in petroleum also parallels the general preference in Nature for angular as opposed to linear structures (for example, the steroids).

Fig. 1

The relative absence of the indoles in petroleum<sup>1</sup> can be rationalized in terms of the much greater reactivity of this class of compounds toward acid and other environments (for example, ref. 2).

### Influence of Gases on the Rate of Evaporation of Water

Two communications on this subject have been published recently. Sechrist<sup>1</sup> found that water containing dissolved carbon dioxide, or surrounded by an atmosphere of this gas, evaporated 15–50 per cent more rapidly than water in the presence of air. Kingdon<sup>2</sup> measured the rates of evaporation of water in the presence of 11 different gases, including hydrogen, oxygen, argon, carbon dioxide and butane. Rates varied over a range of 15 per cent in all gases except hydrogen and helium, which produced rates about 40 per cent less. Kingdon defined a corrected rate of evaporation as the measured rate divided by the diffusion coefficient of water vapour in the surrounding gas. The corrected rate in butane was double that found in oxygen or nitrogen. Other gases also augmented the corrected rate relative to oxygen or nitrogen, except hydrogen or helium, which reduced it five-fold.

Both workers attributed their results to the influence of the gases on the physicochemical state of the water surface. Sechrist suggested that carbon dioxide catalyses the conversion of polymerized liquid water to single molecules, and Kingdon postulated that some gases weaken hydrogen bonding at the water surface. Both these hypotheses imply that certain gases may raise the condensation coefficient of water vapour molecules at a water surface. The existing evidence suggests, however, that this coefficient may be unity<sup>3</sup>. Accordingly a further experiment seemed advisable.

In both the previous experiments the water was held within a shallow pan, so that water vapour migrated upwards from the surface. I have found that reversal of this direction reverses the trend of the observations.

A drop of water, volume 0.0070 ml., was generated at the tip of a thin glass tube attached to a micrometer syringe. The delivery tube was mounted in the rubber stopper of a flask which could be filled with a known dry gas. Rates of evaporation were readily measured by determining residual volumes after known intervals of time. With the flask standing on the bench so that water vapour migrated mainly downwards, drops evaporated 70 per cent more rapidly in hydrogen than in oxygen. In argon the rate was less than in oxygen by about 5 per cent, barely significant in this work. These relative rates follow a trend opposite to that found by Kingdon. With the flask inverted, however, water evaporated 10 per cent more rapidly in argon and 50 per cent more slowly in hydrogen. Thus with water vapour migrating mainly upward results agreeing with Kingdon were obtained.

It is concluded that in all the reported experiments the relative effects observed are influenced more by buoyancy than by any other factor. Whether the underlying mode of diffusion is viscous or turbulent, water vapour departs from a water surface less rapidly if opposed gravitationally and more rapidly otherwise. Thus examination of Kingdon's measurements reveals a strong positive correlation between the density of the surrounding gas and the corrected rate of evaporation.

Kingdon also observed that evaporation proceeded spasmodically except when hindered by hydrogen or helium, and suggested that the phenomenon arose from localized weakening of hydrogen bonds in the water surface. Spasmodic flow, however, is a common consequence of an unstable density gradient, and indeed has been observed within liquid water itself while evaporating<sup>4</sup>.

### Kinetics of Oxygen Reduction on the Amalgam – Acid Solution Interface

In earlier work on the kinetics of electrochemical corrosion on the amalgam–acid solution interface, I found on the basis of experiments carried out with the radioactive tracer method that the oxygen dissolved in the acid solution has a considerable effect on the electrochemical corrosion rate<sup>1,2</sup>. In the presence of dissolved oxygen the following part-processes occur during the corrosion of the amalgamated metal:

As a result of these electrochemical part-processes a so-called mixed potential ( $E^M$ ) develops on the amalgam–acid solution interface<sup>3</sup>, where the dissolution velocity of the amalgamated metal equals the velocity of the oxygen reduction:

$$\left(\frac{dn}{dt}\right)_1^{E^M} = \left(\frac{dn}{dt}\right)_2^{E^M} \quad (3)$$

and the time profile of corrosion can be described by the following differential equation which is characteristic of a reaction of zero order:

$$\left(\frac{dn}{dt}\right)_1^{E^M} = k_1 \quad (4)$$

The following correlation exists between the specific rate constant and the half time of the reaction:

$$k_1 = \frac{C_0}{2t_{1/2}} \quad (4a)$$

where  $C_0$  is the initial concentration of the amalgam.

Fig. 1. Half-time of the corrosion process as a function of the initial concentration of the amalgam. Temperature: 18° C. Volume of the amalgam: 2 ml. (a) Zinc amalgam; (b) thallium amalgam

Fig. 1 shows the half times of the corrosion of zinc amalgams tagged with <sup>65</sup>Zn, and of thallium amalgam tagged with <sup>204</sup>Tl of different concentrations, in a 0.01 N H<sub>2</sub>SO<sub>4</sub> solution saturated with air, as a function of the initial concentration of the amalgam. The value of the rate constants was determined from the slope of the straight lines. These experiments support the assumption that the diffusion of the dissolved oxygen is a rate determining factor in the corrosion of amalgams. The quantity of oxygen which reaches the unit surface of amalgam in unit time can be given by Fick's 1st law:

$$\left(\frac{dn}{dt}\right)_2^{E^M} = \frac{D}{\delta}(c_a - c_s) \quad (5)$$

where  $D$  is the diffusion constant of the dissolved oxygen,  $\delta$  the thickness of the Nernst adhesion layer,  $c_a$  the concentration of the dissolved oxygen in the solution, and  $c_s$  that in the immediate vicinity of the amalgam surface. Due to oxygen reduction on the amalgam surface  $c_s = 0$ , thus from equations (3) and (5) the value of  $k_2$  can be given as:

$$k_2 = \frac{D}{\delta} c_a \quad (6)$$

$c_a$  is constant, because the same quantity of oxygen is reduced on the amalgam-acid solution interface as is dissolved in the acid solution-air interface. If the appropriate values ( $D = 1.98 \times 10^{-5}$  cm<sup>2</sup>/sec,  $c_a = 25 \times 10^{-3}$  g-mole O<sub>2</sub>/ml. and  $\delta = 5 \times 10^{-3}$  cm) are substituted into equation (6) then the value of  $k_2$  will be:

$$k_2 = 9.88 \times 10^{-10} \text{ g-mole O}_2/\text{cm}^2/\text{sec}$$

From the experimental data of Fig. 1a the value of the specific rate for the corrosion of zinc amalgam is:

$$k_1 = 34.6 \times 10^{-10} \text{ g-equiv. zinc/cm}^2/\text{sec}$$

This means that the reduction of 1 g-mole of oxygen results in the corrosion of 4 g-equiv. of zinc, thus in the corrosion of zinc amalgam the cathodic part process can indeed be described by equation (2).

It is known from the work of Kolthoff *et al.*<sup>4</sup> and, more particularly, by that of Bagotzky *et al.*<sup>5</sup>, that the reduction of O<sub>2</sub> on the mercury cathode takes place in two steps according to the following gross equations:

The intermediate product, hydrogen peroxide, formed during the reaction is thermodynamically unstable, as the oxidation-reduction normal potential of the O<sub>2</sub>/H<sub>2</sub>O<sub>2</sub> system is  $E_h^0 = +0.682$  V, and of the H<sub>2</sub>O<sub>2</sub>/H<sub>2</sub>O system  $E_h^0 = +1.77$  V. Thus the presence of H<sub>2</sub>O<sub>2</sub> can be attributed to reaction kinetical reasons: it can be identified only in oxygen reductions where the cathodic reduction on the electrodes requires high activation energies. According to the experimental data of Fig. 1b, oxygen reduction in the corrosion of thallium amalgam proceeds according to equation (7). The value of the experimentally determined rate constant is:

$$k_1 = 17.4 \times 10^{-10} \text{ g-equiv. thallium/cm}^2/\text{sec}$$

thus the reduction of 1 g-mole of oxygen results in the corrosion of 2 g-equiv. thallium.

In order to throw light on the reduction kinetics of amalgams, the time profile of the electrochemical corrosion of amalgamated metals in solutions saturated with inert gas has been examined in the presence of a number of oxidizing agents (IO<sub>3</sub><sup>-</sup>, H<sub>2</sub>O<sub>2</sub>, methylene blue, etc.). The results of these experiments will be reported in another communication<sup>6</sup>.

### Solvent Extraction of Xenon

SOLVENT extraction of xenon has never been reported. Two years ago, one of us (R. K.) noticed that caesium-138 (half-life 32.2 min) was extracted in di-isobutylketon (DIBK) when he was carrying out a rapid solvent extraction separation of short-lived selenium activities from uranium fission products<sup>1</sup>. The caesium-138 activity did not appear in the DIBK phase, if the hydrobromic acid solution of uranium fission products was heated or air-bubbled prior to the extraction of selenium activities into the organic solvent. This phenomenon suggests to us that xenon-138 (half-life 17 min) is extracted into the DIBK phase.

We designed the following experiment to obtain more clear and direct evidence about the possibility of organic solvent extraction of the fission xenon. Direct DIBK extraction of xenon activities from hydrobromic acid solution of uranium fission products causes a greater difficulty, because iodine activities extracted into DIBK phase seriously disturb the  $\gamma$ -ray spectra of xenon nuclides. In this investigation, carbon tetrachloride was used for the extraction of <sup>133</sup>Xe and <sup>135</sup>Xe activities from <sup>133</sup>I and <sup>135</sup>I nuclides which were separated and purified from the fission products in an iodide form.

Fifty mg of UO<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O was irradiated in the *Triga Mark II* reactor of St. Paul's University for 5 h at a neutron flux of  $5 \times 10^{11}$  n/cm<sup>2</sup>/sec. After cooling for one day, <sup>133</sup>I and <sup>135</sup>I were separated along with 20 mg of iodide carrier from the uranium fission products using a standard separation method for iodine<sup>2</sup>. Activities of the final solution, that is, 10 ml. of water containing a few drops of 2 M NaHSO<sub>3</sub>, consists primarily of <sup>133</sup>I, <sup>135</sup>I and their daughters (<sup>133</sup>Xe, <sup>133m</sup>Xe, <sup>135</sup>Xe and <sup>135m</sup>Xe). After standing for several hours, the aqueous phase was shaken for 1 min with 10 ml. of carbon tetrachloride by a mechanical device. The organic phase was then washed twice by shaking vigorously with a 10-ml. portion of water containing a few drops of 2 M NaHSO<sub>3</sub> for 30 sec. Carbon tetrachloride thus obtained was transferred into a polyethylene vial and its  $\gamma$ -ray spectrum was taken on the Technical Measurement Corporation multichannel analyser coupled with 3-in.  $\times$  3-in. thallium activated sodium iodide crystal.

Fig. 1.  $\gamma$ -Ray spectrum of <sup>133</sup>Xe

The spectra obtained are illustrated in Figs. 1 and 2. The photopeaks were found to consist primarily of <sup>133</sup>Xe, <sup>133m</sup>Xe, <sup>135</sup>Xe and <sup>135m</sup>Xe by the  $\gamma$ -ray energies and decay rate measurements.

When carbon tetrachloride containing xenon activities was evaporated off under an infra-red lamp, the residue showed no sign of activities other than the background over the energy range tested. The result also gives additional evidence for the organic solvent extraction of

Fig. 2.  $\gamma$ -Ray spectra of  $^{135}\text{Xe}$  and  $^{135\text{m}}\text{Xe}$ . Successive spectra of  $^{135\text{m}}\text{Xe}$  were taken with an interval of approximately 10 min

xenon. This method enables us to obtain xenon tracers repeatedly from their parent iodine nuclides. Because the carbon tetrachloride extraction system provides a highly specific separation procedure for tracer quantities of xenon, it will apply directly to the separation of short-lived xenon activities from fresh fission products. Thus, the method recorded here would be of particular value for the decay scheme investigations of short-lived xenon isotopes.

### Mechanism of Double-bond Migration catalysed by Group VIII Metal Complexes

RECENT evidence<sup>1</sup> on the palladium (II) catalysed isomerization of olefins has been interpreted as conflicting with earlier mechanisms based on the transfer of hydride<sup>2-5</sup>. Since we have invoked such a mechanism<sup>6</sup>, we should like to point out an alternative interpretation of this evidence, consistent with a hydride transfer mechanism. Our interpretation requires that an abnormally large isotope effect operates in the isomerization of deuterated olefins and that this possibility was overlooked by Davies<sup>1</sup>. Evidence is presented in support of this contention.

Davies isomerized 3-*d*<sub>2</sub>-octene-1 and interpreted his results as requiring a migration of deuterium or hydrogen atoms from C<sub>3</sub> to C<sub>2</sub> and from C<sub>2</sub> to C<sub>1</sub>. He then concluded

that this ruled out both a  $\pi$ -allyl mechanism and a reversible hydride-alkyl equilibrium. Instead, a mechanism involving a carbene intermediate was tentatively proposed.

It should be mentioned that another recent communication<sup>7</sup> proposes a  $\pi$ -allyl mechanism, but we have found it difficult to reconcile such a mechanism with our unpublished observation that isomerization cannot be effected with simple palladium  $\pi$ -allyl complexes under conditions where olefine complexes were effective.

Before excluding the reversible alkyl-hydride mechanism, however, Davies's results must be considered together with the possibility of a large deuterium isotope effect, since reactions involving hydride shifts sometimes show  $k_H/k_D$  values as high as 7 (refs. 8-10).

For an olefine deuterated at the third carbon atom, as used by Davies, the reversible hydride addition mechanism may be represented thus:

Equations (1) and (2) give only a few of the total possible equilibria. Equation (1) is the isomerization step and must give rise to a metal deuteride. Equation (2) represents equilibria which do not give rise to isomerization, but which can result in exchange between metal deuteride and metal hydride. Given the assumption that terminal metalation, as represented in equation (2), is a more probable event than non-terminal metalation, which is a pre-requisite for isomerization, a large  $k_H/k_D$  for breaking carbon-hydrogen bonds will have two effects. First, deuteration at C<sub>3</sub> will lead to a reduction in the rate of isomerization and, secondly, the double-bond will appear to shift by deuterium moving from C<sub>3</sub> to C<sub>2</sub> and hydrogen from C<sub>2</sub> to C<sub>1</sub>, to an extent related to the isotope effect. The first result has not been tested, the second is in agreement with Davies's observations.

In order to obtain further evidence in support of the alkyl-hydride mechanism, we have sought to reverse the effect due to isotopic substitution found by Davies. This can be done by isomerizing hexene-1 deuterated at C<sub>1</sub> and C<sub>2</sub> only. Reactions (1) and (2) then become:

If the breaking of a CD bond is slower than that of a CH, the isotope effect would be expected to reduce the rate of equation (4) relative to equation (2) and of equation (1) relative to equation (3). Thus, in this case the rate of isomerization should be increased and the reaction should

proceed via a  $C_2$  to  $C_1$  hydride shift. Both these results were found.

The deuterated hexene-1 was prepared by the deuteration of hexyne-1 (ref. 11) and was shown by nuclear magnetic resonance to be a mixture of  $C_6H_9CD = CDH$  (64 per cent) and  $C_6H_9CD = CD_2$  (36 per cent). With both  $PdCl_2$  in glacial acetic acid and  $RhCl_3 \cdot 3H_2O$  in isopropyl alcohol the rate of isomerization of the deuterated olefine was about three times faster than that of the protonated olefine (followed by gas phase chromatography and infrared). Also, analysis of products by nuclear magnetic resonance demonstrated that no detectable movement of deuterium occurred during isomerization.

<sup>10</sup> Taylor, S. M., and Halpern, J., *J. Amer. Chem. Soc.*, 81, 2933 (1959).

<sup>11</sup> Lindlar, H., *Helv. Chim. Acta*, 35, 446 (1952).

THE mechanism proposed by Harrod and Chalk, for the palladium II chloride catalysed isomerization of olefines, involves as the effective catalyst an olefine-hydride complex of palladium of such stability that the hydride bond is preserved while the co-ordinated olefine is exchanged with free olefine:

In the earlier publication to which these authors refer<sup>1</sup>, the mechanism which was considered to have been disproved was one in which the hydride complex had a transient existence only. While, therefore, the experimental results can be explained in terms of a large isotope effect, such an explanation is based on the existence of such a relatively stable hydride. My approach differed from that of Chalk and Harrod essentially in that, despite the analogue of the cobalt carbonyl hydride, I rejected the possibility of a stable hydride complex, or, in fact, one in which the hydride originated other than from the isomerizing olefine. An isotope effect would, of course, be expected to alter the reaction rate and this was in fact observed, the rate of isomerization of the  $C_2$  deuterated olefine being markedly slower. However, by such a mechanism, even a large isotope effect would not have prevented deuterium from appearing ultimately at the terminal carbon atom.

Although the assumption that the catalyst is not converted into a stable hydride may possibly prove to be incorrect, it is a conclusion which seems reasonable in view of the evidence available. Thus the hydride complexes of palladium have been reported to be extremely unstable.  $(PdHCl)(PEt_3)_2$ , in which the hydrogen is under the stabilizing influence of two groups of high ligand field strength, could nevertheless not be prepared by methods analogous to those which led to the platinum analogue<sup>2</sup>. Furthermore, a recent study of the kinetics of isomerization of allyl benzene with a palladium II chloride catalyst has led to the conclusion that if the effective catalyst is in fact a hydride complex, then all, and not just a small

fraction, of the catalyst will be present in this form. So far, attempts to detect such hydrogen in the nuclear magnetic resonance spectrum, during the course of the reaction, have proved fruitless<sup>3</sup>. In view of the very large and unique chemical shifts which are characteristic of such hydrogen<sup>4</sup>, this would appear to be surprising if the catalyst were present in any quantity as a hydride complex.

### Chelation of Ferrous Sulphate Solutions by Desferrioxamine B

DESFERRIOXAMINE B is a specific iron complexing agent originally obtained from an iron-bearing metabolite of *Actinomyces* (*Streptomyces pilosus*)<sup>1,2</sup>. It is available for clinical use as 'Desferal'® (desferrioxamine B methane-sulphonate) and has undergone extensive evaluation in the treatment of chronic iron overload states<sup>3</sup>. The compound, a trihydroxamic acid derivative, has a strong affinity for ferric ions (stability constant  $\log K = 30.6$ ) with which it reacts to form a complex known as ferrioxamine, but it is reported to form relatively little complex with ferrous ions<sup>4</sup>. During the course of investigations involving the use of desferrioxamine B in the treatment of acute iron poisoning in dogs<sup>5</sup>, it was necessary to determine the extent to which ferrous ions form a complex with the chelate. In this communication we wish to present preliminary results relative to the ability of desferrioxamine B to complex with ferrous iron.

The complex formed when ferrous ions are reacted with desferrioxamine B appears to be the same as when ferric ions are reacted. The evidence is as follows: (1) Ferrous ions react with desferrioxamine B in a 1 : 1 molar ratio as estimated by the continuous variation method of Job<sup>6</sup> as modified by Vosburgh<sup>7</sup>. Ferric ions react in a similar manner. (2) The spectral absorption curve (220–700 mμ) of the complex formed when ferrous sulphate and desferrioxamine B are reacted (in the presence of ascorbic acid) is identical to that obtained when ferric perchlorate and desferrioxamine B are reacted (Fig. 1). (3) The molecular extinction coefficient of the iron–desferrioxamine complex formed by reacting either ferrous or ferric ions with desferrioxamine B was 2,480. These measurements were made using a 0.05 M *tris* buffer (pH 7 at 37° C) with a Beckman model DB spectrophotometer. (4) The complex formed by reacting either ferrous sulphate ( $2 \times 10^{-4}$  M in 1 per cent ascorbic acid) with desferrioxamine B ( $2 \times 10^{-4}$  M) or ferric chloride ( $2 \times 10^{-4}$  M) with desferrioxamine B ( $2 \times 10^{-4}$  M) yielded ferric sulphate when reacted with sulphuric acid at a ratio of 6 : 1 (Fig. 2).

The following evidence suggests that the reaction between ferrous ions and desferrioxamine B involves an oxidation to the ferric state prior to complexation: (1) No spectrophotometric evidence (220–760 mμ) for the formation of a complex occurred when ferrous sulphate and desferrioxamine B were reacted under oxygen-free conditions. An oxygen-free medium was accomplished by bubbling nitrogen which had been previously passed through a saturated pyrogallol solution through the ferrous sulphate (in 1 per cent ascorbic acid) and the desferrioxamine B solutions for 10 min prior to, and after, mixing them. Subsequent exposure of this mixture to air or oxygen led to the formation of the ferric complex.

\* Trade name: CIBA Pharmaceutical Co., Summit, New Jersey.

Table 1. EFFECT OF pH ON THE REACTION OF FERROUS SULPHATE WITH DESFERRIOXAMINE *B* METHANE SULPHONATE IN THE PRESENCE OF ATMOSPHERIC OXYGEN AT 25° C

pH	4.28	5.30	5.80	6.70	7.20
Velocity constant ( $K_1$ )	0.0158	0.226	2.585	4.665	6.860
$t^{1/2}$ (min)	43.73	3.07	0.268	0.149	0.010

The calculations were based on equations for first-order kinetics.

(2) The reaction of either ferrous or ferric ions with desferrioxamine *B* was not affected by the presence of the reducing agents, ascorbic acid, sodium sulphite, and hydroxylamine hydrochloride. However, mercapto-acetic acid, sodium thiosulphate and sodium dithionite prevented the reaction of ferrous and ferric ions with desferrioxamine *B* in the presence of oxygen at pH 7. Normally, all six reductants are capable of reducing and maintaining iron in the ferrous state. However, thiosulphate, dithionite and mercapto-acetate are the more powerful reductants.

Further investigations indicate that the reaction between equimolar concentrations of ferrous ions and desferrioxamine is pH dependent as is the reaction between ferric ions and desferrioxamine (Fig. 3). An acetic acetate buffer was used to establish pH values below 7. A *tris* buffer was used to establish pH values of 7 and above. The reaction mixtures were incubated at 37° C for 20 min prior to the estimation of the ferrioxamine concentration. As shown, the reaction between ferrous ions and desferrioxamine goes to completion at pH values above 5 ( $I = 0.05$ ), whereas the reaction between ferric ions and desferrioxamine goes to completion below a pH of 5. Possible explanation for the higher degree of complexation of ferrous salts at pH values above 5 is that at high pH values the oxidation of ferrous ions to the ferric form is accelerated. Less than maximum complexation of ferric ions and desferrioxamine *B* occurs at high pH values because fewer ferric ions are free to react with desferrioxamine because of hydration and the subsequent strong tendency towards the formation of insoluble hydroxides.

Maximum formation of ferrioxamine was achieved at a low pH when the molar ratio of ferrous sulphate to desferrioxamine was 8:1 or the molar ratio of desferrioxamine to ferrous sulphate was 7:1. The reaction rate of

Fig. 1. Spectral absorbance curve for ferrioxamine ( $2 \times 10^{-4}$  M) formed by reaction of ferric perchlorate with desferrioxamine

Fig. 2. Spectral absorbance curves of products formed by the reaction of ferrioxamine and iron salts with  $H_2SO_4$ . ...,  $Fe^{++}$  formed complex +  $H_2SO_4$ ; ---,  $Fe^{+++}$  +  $H_2SO_4$ ; —,  $Fe^{+++}$  formed complex +  $H_2SO_4$ ; — — —,  $Fe^{++}$  +  $H_2SO_4$ .

Fig. 3. Effect of pH on the formation of ferrioxamine from  $Fe^{++}$  and  $Fe^{+++}$  salts

ferrous sulphate with desferrioxamine *B* is increased over 4,000-fold with an increase in pH from 4.28 to 7.20 (Table 1). (Equations were used for first-order kinetics.)

The foregoing results strongly suggest that desferrioxamine *B* is highly specific for ferric ions and that it reacts with ferrous ions normally under conditions which permit or facilitate prior oxidation to the ferric form. However, the possibility does exist that a colourless unstable ferrous complex is formed between ferrous ions and

desferrioxamine B and that in the presence of oxygen the ferrous complex is rapidly oxidized to the ferric complex (ferrioxamine). In either case, it appears that this oxidation is catalysed by desferrioxamine B and the catalysis is inhibited by only the more powerful reducing agents.

## BIOPHYSICS

### Small-angle X-ray Diffraction on Cross-striated Muscle

As an object for testing circular aperture systems for small-angle cameras<sup>1</sup> we used dried bovine skeletal muscle. The main features of the test photographs seem to us worth reporting as, so far as we are aware, some of them have not been reported before.

In Fig. 1 the small-angle diagram obtained from bovine skeletal muscle is shown schematically (fibre axis vertical, perpendicular to direction of the primary beam, copper-K $\alpha$ -radiation, 50 kV, 20 m.amp, 7  $\mu$ m nickel foil, about 50 h exposure time).

Fig. 1. Small-angle diagram of the dried skeletal muscle of ox (schematic)

There are three fairly sharp reflexions  $R_1$ ,  $R_2$ ,  $R_3$  with intensities strong, weak, medium corresponding to spacings  $d_1 = 60.0 \pm 0.2$  Å;  $d_2 = 51.4 \pm 0.2$  Å;  $d_3 = 49.2 \pm 0.2$  Å respectively. The fact that these reflexions do not spread out perpendicular to the equator indicates that the objects responsible for them must be almost perfectly aligned with respect to the fibre axis.

At a somewhat bigger angle there is a sickle-shaped reflexion the maximum of intensity of which is on the equator and comparable with that of  $R_1$ . Its position corresponds to a spacing of about 40 Å, but varies from one sample to the other by about  $\pm 2$  Å. The value 40 Å is that most frequently obtained. The considerable length of the sickle indicates that the objects giving rise to it are aligned rather badly about the fibre axis as the preferred orientation.

On the meridian 10 orders corresponding to a period of 54 Å show up. The first order is, however, split into four points, each of which is split further into a pair of closely neighbouring reflexions. This is in agreement with a diagram obtained by Cohen and Hanson<sup>2</sup> from dried fibres of F-actin. According to Bear<sup>3</sup> the existence of an essentially larger period (of 350–420 Å) may be concluded from variations of the value of the 54 Å-spacing as deduced from the different orders. From precise measurements of the positions of the 10 registered orders we obtained a value of  $406 \pm 5$  Å for this large period.

In diagrams of dried muscle a rather intense anisotropic continuous small-angle scattering occurs close to the primary beam (Fig. 1). This extends over a considerably larger range perpendicular to the fibre direction than parallel to it. As the small-angle scattering gives a reciprocal image of the scattering particles, it may be concluded that in dried muscle small-angle scattering is due to oblong particles with their main extension essentially parallel to the fibre axis. A double logarithmic plot of the scattering curve—as suggested by Porod<sup>4</sup>—is in agreement with this assumption. This has in its central portion a straight part with slope  $-1.4$ , indicating that the scattering particles have the shape of long rodlets. A quantitative discussion of the scattering curve would, however, not be justified.

A search of reflexions corresponding to the various orders of a 420 Å period as observed by Huxley on living muscle was without result, presumably because they become swamped by the intense continuous small-angle scattering.

Finally, we wish to put on record some differences of the X-ray diagrams obtained from muscle allowed to swell in distilled water after drying as compared with the dry muscle.

Small-angle scattering recorded with a camera with linear slit system has a peak corresponding to a spacing of 180 Å superimposed on the continuous scattering. The diffuse reflexion which for the dried muscle corresponds to a spacing of 4.6 Å is shifted in the soaked muscle to 3.35 Å. The meridional 5.14 Å and 1.49 Å reflexions of the wide angle diagram of dried muscle appear not to be influenced by swelling, whereas the equatorial 9.8 Å reflexion of dried muscle is shifted to 11 Å after swelling.

## BIOCHEMISTRY

## Measurement of Chenodeoxycholic Acid and Deoxycholic Acid or their Derivatives in a Mixture

THE measurement of the dihydroxycholic acids found in human bile (chenodeoxycholic acid,  $3\alpha,7\alpha$ -dihydroxycholic acid and deoxycholic acid,  $3\alpha,12\alpha$ -dihydroxycholic acid) or of their ester derivatives or conjugates with glycine or taurine has always presented difficulties where the original material to be analysed contains both acids or derivatives of them. Before 1953, the only method available depended on the repeated precipitation of the barium salt of chenodeoxycholic acid. Its value may be gauged from the fact that until this time chenodeoxycholic acid was considered to be a very minor constituent of human bile, a belief shown to be erroneous by Wootton<sup>1</sup> in 1953 when he separated methyl cholate from the two dihydroxy methyl esters by a column chromatographic procedure which utilized silica gel as the supporting medium and pentane/hexane and petroleum ether as the developing solvents. The proportions of methyl chenodeoxycholate and methyl deoxycholate in a mixture could be readily estimated by an investigation of the infra-red spectra of solutions in carbon disulphide. By these means, Wootton demonstrated that chenodeoxycholic acid was, in fact, a major constituent of human bile. The method is relatively insensitive compared with later methods of bile acid measurement which have been devised, requiring about a milligram of the mixed dihydroxy compounds to ensure reasonable accuracy of estimation of the proportion of the two esters.

Later, Sjövall<sup>2</sup> found that by using *iso*-propyl ether:heptane (20:80) as the mobile phase and 70 per cent acetic acid as the stationary phase, separation of the two dihydroxy acids on paper was obtained after the system had operated for 18 h. Pure heptane was also found to be suitable as the mobile phase, effective separation being obtained after 72 h. Such a system was found to be capable of handling quantities of the order of several micrograms. The glycine conjugates of chenodeoxycholic and of deoxycholic acids were also reported by Sjövall to have been separated by paper chromatography using *iso*-propyl ether:heptane (80:20 or 85:15) as the mobile phase and 70 per cent acetic acid as the stationary phase. However, no separation could be

achieved between the taurine conjugates of the two dihydroxy bile acids. In the work reported by Sjövall, estimation of the different bile acids was carried out by measurement of the ultra-violet adsorption in 65 per cent aqueous  $H_2SO_4$  of the acids eluted from the paper.

The fluorescence of the bile acids and their derivatives in concentrated  $H_2SO_4$  has been known for many years, the fluorescence of cholic acid in  $H_2SO_4$  being reported by von Hammarsten<sup>3</sup> in 1922. However, it was not until many years later that Turner *et al.*<sup>4</sup>, Wootton and Osborn<sup>5</sup> and Osborn<sup>6</sup> reported in detail the fluorescent properties of the major human bile acids and their derivatives in  $H_2SO_4$  under various conditions of development of fluorescence with respect to temperature and time.

A method based on the fluorescence properties of methyl chenodeoxycholate and methyl deoxycholate, involving the measurement of the fluorescence of a mixture in  $H_2SO_4$  at 4° C and 100° C, enables the proportions of each in a mixture to be accurately determined at concentrations as low as 0.5  $\mu g/ml$ .  $H_2SO_4$ . The factor increase in fluorescence from 4° C, after standing at this temperature for 1 h, to that obtained after subsequent heating at 100° C for 20 min, is about 9 for methyl chenodeoxycholate, whereas with methyl deoxycholate the factor increase is about 33. Intermediate rises in fluorescence are shown by mixtures of the two compounds in varying proportions, when similarly treated (Fig. 1). When this method is used for analysing a mixture of the two dihydroxy compounds, it is unnecessary to determine the factor increase in fluorescence for other than the pure substances, since the necessary intermediate points on the graph may be obtained by assuming the fluorescences are additive.

It is necessary when working over such a wide range of fluorescence to use two quinine sulphate reference standards. The fluorescence developed at 4° C, 1 h, is measured against the lower standard and that at 100° C, 20 min, against the second standard which is ten times as concentrated as the lower one. Once the relative proportions of chenodeoxycholate and deoxycholate in a mixture have been determined, the absolute amounts of each may be estimated by preparing a mixed standard of the two in the same ratio, fluorescence being induced by heating an  $H_2SO_4$  solution at 100° for 20 min.

## Amino-acids on Hands

RECENT methods for the determination of amino-acids by ion-exchange chromatography at the  $10^{-8}$  and  $10^{-9}$  mole levels<sup>1,2</sup> are now able to give a quantitative measure of observations that have hitherto been of a qualitative nature<sup>3,4</sup>. For example, it is well known that finger-marks on paper chromatography are to be avoided because they are deeply coloured on treatment with ninhydrin reagent. It is probably less well appreciated that amino-acids might be introduced, some considerably in excess of the  $10^{-8}$  mole level, at any or all steps of preparative manipulation prior to chromatography, and these contaminants would then be unwittingly measured along with the material of analytical interest.

Work that necessitated very rigid exclusion of accidental contamination led to the following experiments. (1) A

Fig. 1. Amino-acids found by ion exchange chromatography in a single thumb print made on a wet glass surface. For visual comparison of peaks, the amount of lysine (0.011  $\mu$ mole) is indicated on the figure. On the abscissa, 1 min is equivalent to 0.5 ml. of column effluent volume; column diameter, 0.636 cm; volumetric input to column, 30 ml. per h

dry beaker (25 ml.) received a single print from a dry thumb, the hands having been washed 2 h previously; average casual laboratory conditions were thus approximated. The print was then washed into a flask with water, the water was evaporated and the dried residue was transferred with 0.1 N HCl to an ion exchange column. Analysis was carried out by means of the fully automatic procedure of Hamilton<sup>1</sup>, which uses a single column of high resolving power, packed with narrowly classified spherical particles of 17.5  $\mu$  diameter of Dowex 50  $\times$  8 (refs. 5-7). In this chromatogram (not shown) 17 constituents were revealed of the order of  $5 \times 10^{-9}$  to  $2 \times 10^{-10}$  moles; proline, citrulline,  $\alpha$ -amino-*n*-butyric acid, cystine and methionine were missing. (2) A beaker rinsed with water to wet the walls received a single thumb print. This print was analysed as described. The chromatogram obtained is shown in Fig. 1, and the amounts of amino-acids that were found are shown in Table 1.

Table 1. AMINO-ACIDS OF A SINGLE WET THUMB PRINT

Amino-acid	$\mu$ moles	Amino-acid	$\mu$ moles
Taurine	0.001	Valine	0.013
Urea	0.470	Cystine	<0.0001
Aspartic acid	0.023	Methionine	0.002
Threonine	0.018	Isoleucine	0.008
Serine	0.106	Leucine	0.011
Glutamic acid	0.009	Tyrosine	0.006
Proline	0.011	Phenylalanine	0.007
Citrulline	0.004	Ammonia	Off scale
Glycine	0.071	Ornithine	0.034
Alanine	0.029	Lysine	0.011
$\alpha$ -amino- <i>n</i> -butyric acid	<0.0001	Histidine	0.018
		Arginine	0.005

Several observations can be made. Of the amino-acids, the serine peak was the largest; asparagine is not resolved from serine in this system of analysis and its presence or absence was not established. It is interesting to note that Embden and Tachau<sup>8</sup> isolated and identified serine from sweat in 1910. A very small shoulder on the rear of the serine peak was probably due to glutamine; its identity was not, however, established. Glycine was the next most abundant amino-acid. Aspartic acid was present in much greater relative amounts than in normal plasma. Citrulline and ornithine were also present in relative amounts somewhat greater than that usually encountered in plasma. Since these two amino-acids, as demonstrated here on skin surface, are not found in ordinary proteins,

their presence together in materials (other than body fluids) may suggest, but certainly does not prove, possible finger contamination. Cystine was virtually absent; it was detected with certainty only in very concentrated finger washings. Methionine was present in very low concentration; beta-alanine was absent. In general, these findings were similar for the finger washings of three other subjects, one of non-laboratory personnel.

In the final experiment, the fingers and palms of both hands were washed in 200 ml. of water and the washings were concentrated to 1 ml. volume; 0.5 ml. of the concentrate was analysed. The common amino-acids were very abundant and many other ninhydrin positive unknown substances became apparent. The largest of these unknown peaks is numbered 1 to 32 on the chromatogram; in addition to these, 10 other lesser peaks were noted but are not shown. No. 10 plus the small precystine peak and 15 and 16 denote base line changes associated with solvent front phenomenon due to buffer changes.

After hydrolysis for 24 h in boiling 6 N HCl under reflux in a stream of nitrogen, the amounts of aspartic acid, serine, threonine, glutamic acid, proline, glycine, alanine, valine, cystine, methionine, isoleucine, leucine, tyrosine, phenylalanine, lysine, histidine and arginine were increased. This result was to be expected as the washings were not filtered to remove minute scales that might have been shed from the skin, or bacteria. The method is capable of detecting the hydrolytic products from 1  $\mu$ g of protein. Hydroxyproline was absent from the hydrolysate. After hydrolysis the amounts of taurine,  $\alpha$ -NH<sub>2</sub>-butyric acid, and ornithine were unchanged, while urea and citrulline were somewhat reduced. Of the numbered peaks, 1, 20, 21 and 26 were essentially unchanged by hydrolysis; 14 was increased; 5, 7 and 30 were greatly diminished; the rest disappeared. Presumably, many of these are low molecular weight peptides or other bound forms of amino-acids.

These results show that hand contamination of specimens could lead to erroneous findings. From a medical or clinical point of view, they suggest a further enquiry into the excretion or secretion of amino-acids by the skin, in health and disease; some similarity between skin and kidney, both ectodermal in origin, might be expected. The possibility that internal metabolic amino-acid abnormalities might be reflected in amino-acid distribution on the skin has not apparently been explored. The methods usually used to collect urine from very young infants may be subject to error due to skin contamination, as would blood samples from finger, heel or ear pricks.

## Influence of D<sub>2</sub>O on Resistance of Plant and Animal Cells, Cellular Models and Actomyosin to some Denaturing Agents

ACCORDING to the denaturation theory of injury<sup>1,2</sup> the response of a cell to the effect of various agents is determined by conformational changes induced in macromolecules of protoplasmic proteins. In seeking to define conditions which would increase the resistance of various proteins to denaturing influences and to determine their effect on the stability of living cells, our attention was directed to the influence of D<sub>2</sub>O on proteins. Deuterization increases the resistance to heating in certain proteins, such as ribonuclease<sup>3</sup>, gelatin<sup>4</sup>, collagen<sup>5</sup> and keratin<sup>6</sup>. We investigated the effect of D<sub>2</sub>O on resistance to heating and high hydrostatic pressure in plant (leaf epidermis of *Campanula persicifolia* L.) and animal (ciliated epithelium of the palate in the frog *Rana temporaria*) cells on one hand, and in protein preparations (muscle actomyosin of frogs and glycerin models of frog ciliated cells<sup>7</sup>) prepared according to Hoffmann-Berling<sup>8</sup>, on the other. The following resistance indices of cells and proteins were studied in the media containing D<sub>2</sub>O (test) or H<sub>2</sub>O (control): (a) the temperature at which 5-min heating irreversibly stopped protoplasmic streaming in plant cells; (b) the hydrostatic pressure which, after 5 min, stopped protoplasmic streaming in the same cells; (c) the minimal pressure which, after 5 min, stopped protoplasmic streaming in the plant cells; (d) the temperature at which ciliary movement of the frog cells ceased after 5 min or 1 sec heating; (e) the hydrostatic pressure which stopped ciliary movement after 5 min; (f) the degree of suppression of actomyosin ATPase activity after 15-min heating at 40° C; (g) the degree of suppression of actomyosin ATPase activity after 15 min at 1,300 atm.; (h) the temperature at which, after 5 min, the movement of glycerin models of ciliated epithelium in the presence of ATP is prevented. We also investigated the influence of the duration of the contact between D<sub>2</sub>O and cells, cellular models and actomyosin, on their resistance to heating and high hydrostatic pressure. The results were as follows:

(a) The thermostability of plant cells proved to be considerably higher in D<sub>2</sub>O than in H<sub>2</sub>O: the criteria being met at 52.7°–53.0° C in the controls, and 55.4°–55.7° C in the tests (99 per cent D<sub>2</sub>O). The increase in heat resistance was independent of whether the cells were kept in D<sub>2</sub>O for 4–5 h or for only 5 min before heating.

(b) Deuterization increases the resistance of plant cells to high hydrostatic pressure. In 99 per cent D<sub>2</sub>O protoplasmic streaming was irreversibly stopped only when the cells were subjected to 2,300 atm., compared with 2,000 atm. in controls. The difference of 300 atm. is statistically significant.

(c) In D<sub>2</sub>O a complete but reversible stoppage of protoplasmic streaming in the same cells occurred after 5 min at a pressure of 1,680 atm., and in H<sub>2</sub>O after the action of 1,500 atm. The difference is statistically significant.

(d) Living ciliated cells were investigated in Ringer solution with H<sub>2</sub>O (RH<sub>2</sub>O) or D<sub>2</sub>O (RD<sub>2</sub>O 99, 87 or 43 per cent). The temperature at which ciliary movement ceases after 5 min is constant for each species. For *R. temporaria* it proved to be 41.8°–42.0°. 87 per cent RD<sub>2</sub>O increased this value by 1.8°–2.2°. Variation in the duration (0–24 h) of preliminary contact between cells and D<sub>2</sub>O before heating does not significantly affect the degree of stabilization. Moreover, even after a 1-sec heating of ciliated cells in 99 per cent RD<sub>2</sub>O without preliminary soaking, that is, when the contact of cells with D<sub>2</sub>O lasted only 1 sec, their thermostability proved to be higher than after a 1-sec heating in RH<sub>2</sub>O. In RH<sub>2</sub>O ciliary movement ceases after a 1-sec heating at 52.1° and in 99 per cent RD<sub>2</sub>O, at 54.2° C. If samples of mucosa are kept for 4 h in 99 per cent RD<sub>2</sub>O before 1-sec heating, the stoppage of ciliary movement occurs at the very similar temperature of 54.8° C.

(e) The resistance of ciliated cells to hydrostatic pressure is increased in RD<sub>2</sub>O. In RH<sub>2</sub>O ciliary movement is suppressed by 5 min at 1,650–1,700 atm., and in RD<sub>2</sub>O at 1,850–1,900 atm. Variation in the duration of preliminary contact between cells and D<sub>2</sub>O before the injurious action of pressure (from 0 to 24 h) does not influence the magnitude of the stabilizing effect. The effect of stabilization decreases when D<sub>2</sub>O concentration in the medium falls from 87 per cent to 43 per cent.

(f) Heating actomyosin at 40° C for 5 min causes a 63 per cent repression as compared with the initial value. The same heating in the medium containing 50 per cent D<sub>2</sub>O causes a 25 per cent repression of actomyosin activity.

(g) After 15 min action at a hydrostatic pressure of 1,300 atm., actomyosin activity was decreased by 74 per cent. Similar treatment of actomyosin in the media containing 50 per cent D<sub>2</sub>O caused only a 43 per cent decrease of activity.

(h) The resistance of ciliated epithelium models to heating for 5 min in solutions containing D<sub>2</sub>O (0.12 N KCl in 87 per cent D<sub>2</sub>O) increases from 39.4° in the control (heated in 0.12 N KCl in H<sub>2</sub>O) to 41.9° in the test. Decreasing the D<sub>2</sub>O concentration down to 45 per cent reduced the protective effect.

Detsherevsky and Kornienko<sup>9</sup> showed that the temperature which induced heat contracture of frog muscles increased by 5.6° C if H<sub>2</sub>O was replaced by D<sub>2</sub>O in Ringer solution. Variation in the time of D<sub>2</sub>O action from 5 min to 18 h did not affect the result. An increase in resistance was detected 60 sec after the immersion of muscles in the media containing D<sub>2</sub>O.

It has been shown that D<sub>2</sub>O protects cells of *E. coli* from γ-rays<sup>10</sup>. Poliovirus was found to endure the super-optimal temperature of 40° C better in D<sub>2</sub>O than in the medium with H<sub>2</sub>O<sup>11</sup>. Thus D<sub>2</sub>O increases the resistance of isolated proteins and of living cells to different injurious agents. This protective effect is not universal: in our experiments D<sub>2</sub>O did not change the resistance of plant cells to ethanol.

It is difficult to define the mechanism of this protective action of D<sub>2</sub>O. Some investigators are prone to explain the stabilizing effect of D<sub>2</sub>O on proteins by the replacement of hydrogen atoms in H-bonds in protein molecules by stronger D-bonds resulting in a greater stability of the native configuration of molecules. Our data indicating the independence, or relative independence, of the stabilizing effect of cells and proteins from the duration of their contact with D<sub>2</sub>O seem to contradict this. The replacement of H in H-bonds in protein molecules by D under normal conditions requires many hours. In these experiments, however, contact with D<sub>2</sub>O took place in the presence of denaturing agents. It seems quite probable that in such conditions deuterium exchange proceeds more rapidly and contributes to the stabilization in resistance to injury.

On the other hand, the replacement of H<sub>2</sub>O by D<sub>2</sub>O involves some changes in the structure of the water itself and in the dissociation constant of dissolved substances. This may affect many bonds, providing for a secondary, tertiary and quaternary structure of protein molecules and thus changing their stability to denaturing agents. A similar effect of D<sub>2</sub>O on the resistance of isolated proteins and living cells to injury is a new argument in support of the suggestion that the resistance of cells to various injurious agents is determined by the stability of the configuration of the protein molecules of the protoplasm. The stabilizing effect of D<sub>2</sub>O on cells and proteins goes with the capacity of D<sub>2</sub>O to repress the physiological activity of cells. There are, in the literature, numerous references to the repressive effect of D<sub>2</sub>O on the growth, reproduction and other manifestations of the metabolic activity of cells. In our experiments on the action of D<sub>2</sub>O we frequently observed a decrease in the rate of protoplasmic streaming in plant cells and of ciliary movement in animal cells. In 15 per cent D<sub>2</sub>O (before the

beginning of the enzymatic reaction the protein was kept for several minutes in the medium containing 50 per cent  $D_2O$  ATP activity of actomyosin was decreased by  $12.9 \pm 4.2$  per cent. The comparison of these facts permits the suggestion that the stabilizing effect of  $D_2O$  on the molecular structure of cell proteins is the basis of the suppressive effect of  $D_2O$  on vital functions of cells. At the present time the significance of conformational changes of proteins for the normal life of cells becomes more and more evident<sup>12,13</sup>. Decrease in the flexibility of molecules would be expected to inhibit their biochemical activity and, at the same time, increase their resistance. There is evidence to confirm that increased sensitivity of cells goes with a high level of metabolism. This idea forms a basis of Childe's theory about physiological gradients. Similar relationships were more than once observed in our laboratory when experimenting with cold and heat hardening of plant cells<sup>14</sup>.

### Potential Significance of Free Taurine in the Diet

In previous investigations it has been shown that free taurine is present in the tissues of both invertebrate and vertebrate species<sup>1,2</sup>. However, published taurine analyses of specific food items or animal tissues, used as food, have been extremely limited<sup>3,4</sup>. Various reasons may be put forward to account for this lack of information. First,

in man, taurine has not been shown to have an active function, other than that of conjugation with bile-acids<sup>5</sup>. Secondly, more than forty years ago, Schmidt showed that the oral administration of taurine to human subjects resulted in the prompt urinary excretion of 60-87 per cent of the taurine sulphur in the organic form. It was presumed that the organic sulphur-containing constituent in the urine was free taurine<sup>6</sup>. Thirdly, until this investigation, the only reported toxic effect of taurine occurred in rabbits; while in man and other animals it has been shown to be non-toxic even in high dosage<sup>7,8</sup>.

During present examination of the effects of sulphur-containing compounds, from dietary sources, on patients suffering from psoriasis, it has been found that taurine induces a predictable response. After 2-g oral doses of taurine, intense itching occurs in about 1 h, and this persists for a variable time, usually 24-28 h. If skin lesions are present at the time of the test, these increase in redness and commence to scale profusely about 18 h after the taurine has been given. However, the initial itching response is independent of the extent of the dermatosis and may be elicited even in those in complete remission. When normal control subjects receive the test dose of taurine, no itching or other adverse effect has been demonstrated.

These clinical observations suggested that taurine had some function in the maintenance and possibly in the induction of the psoriatic state. It was conceived that in addition to the taurine produced endogenously by the catabolism of methionine and cystine<sup>9</sup>, free taurine might be ingested continuously in the diet. This line of deduction prompted an analysis of foods for their taurine content. Initially the investigation was limited to animal protein sources, but it is now being extended to include vegetable protein foods.

Preparation of the foods consisted in separation of the edible portion and dissection removal of fat from meats. The wet weight of each solid item was determined, and it was then homogenized with de-ionized water, using a Waring blender with a metallic semi-micro attachment. During the homogenization procedure, 10 ml. of de-ionized water was added for each 5 g of solid and the mechanical disruption was continued for 5 min. Aliquots of 20 ml. of the homogenate were de-proteinized by the Somogyi method, centrifuged and filtered through Whatman No. 42 paper. Selective passage of the zwitterion of taurine through both an anion and a cation exchange resin has been used as a basis for the subsequent assay. 4-ml. portions of the filtrate were passed through chromatographic columns, 30 cm x 10 mm in size, containing 'Dowex 50W-X4' (200-400 mesh) 4 ml. in the hydrogen form and 'Dowex 1-X8' (200-400 mesh) 2 ml. in the chloride form. The preparation of the columns was carried out according to Garvin's specification<sup>10</sup>. Each column was washed with two 1-ml. portions of de-ionized water. Quantitative analysis of taurine in the effluent was performed by Sörbo's method; utilizing the colour reaction between taurine and ninhydrin<sup>11</sup>. Each

Table 2. LEACHING OF TAURINE FROM FOODS BY BOILING

Item	Sample No.	Content of uncooked food	Retention in boiled samples	Losses in cooking fluid
Beef (lean round)	1	46.4	5.8	20.4
	2	47.2	0.3	20.4
Pork liver	1	22.8	5.4	25.9
	3	11.0	3.0	8.4
Lamb kidney	1	15.0	5.5	2.3
	2	12.8	4.7	2.5
Oyster	1	123.0	11.4	195.0
	6	76.0	16.0	92.0
	7	88.0	9.0	84.0

The taurine content of the raw and boiled foods is expressed as mg/100 g of edible portion—wet weight. The losses in the cooking fluid refer to mg from 100 g of food boiled in 100 ml. of water for 15 min. In food samples, such as oysters, where the cooking fluid contains more taurine than the raw material, the excess represents taurine freed from chemical combination by the boiling procedure. The latter assumption has been verified by hydrolytic methods followed by chromatography.

analysis was checked for specificity by paper chromatography of concentrates of the column effluent. A one-dimensional descending system was used with a solvent of tertiary butanol:methyl ethyl ketone:pyridine:water in the volumetric ratio 40:40:1:20 (ref. 12). Taurine spots were identified on the paper by ninhydrin, 0.25 per cent in acetone, and also by the specific colour reaction between taurine and *O*-phthalaldehyde<sup>13</sup>. Liquid food samples were measured by volume and the analytical procedures were carried out as already described here, starting with the de-proteinization step.

In the case of foods, where the effect of cooking methods on the taurine content was being determined, the original sample was divided into three portions, each of which was then weighed. One portion was then homogenized, according to the method previously described; a second portion was boiled for 15 min in a known volume of de-ionized water and a third was baked in aluminium foil for 30 min at 350° F. The cooked portions were then homogenized and the taurine content of these samples and of the boiling fluid was assayed. The final taurine values were expressed as mg/100 g of edible food in the case of solids, and as mg/100 ml. in the case of liquids.

It can be seen from Table 1 that the highest taurine values have been found in sea foods from invertebrate phyla, but that other animal protein foods also contain significant quantities of the amino-acid. Apparently a part of the taurine is destroyed by heat; however, it is of greater interest that taurine is leached out by the boiling procedure. The extracted taurine can be recovered from the cooking fluid (Table 2). It is our intention to evaluate the effects of various food preservation techniques on the taurine contents of meats and fish, because it has previously been shown that, in the case of codling, 'icing' of the fresh muscle depletes the taurine, owing to the fact that it is leached out into the ice water<sup>14</sup>.

Our immediate concern in this investigation lies in the possibility that taurine may, in pathological circumstances, exert an active and toxic biochemical function in the human body. In patients with psoriasis, as indeed in normal persons, it has now been established that taurine may be ingested in large amounts in the daily diet. The actual amount will vary with food sources and with the cooking methods used. An investigation of taurine excretion and retention in normal and psoriatic subjects is in progress. The effects of high and low taurine diets are also being evaluated.

Several interesting questions arise from an examination of our preliminary data. Whereas it is known from the work of marine biologists and physiologists that taurine has active chemical and physico-chemical functions in the tissues of primitive phyla<sup>15</sup>, little is understood of its utilization in higher animals. In addition to the proposed function of taurine as a regulator of osmotic pressure in marine organisms<sup>16</sup>, phosphotaurine has been isolated from the marine worms and it is believed that this phosphagen, of low thermodynamic potential, may be utilized in the contraction of slow muscles. It is known

that taurine and its deaminated derivative isethionic acid are present in the squid axoplasm, and the synthesis of isethionic acid from taurine has been demonstrated in the dog's heart<sup>17,18</sup>. In the former case, the taurine may play a part in nerve transmission, and in the latter it is important in the transmission of cardiac impulses<sup>17,19</sup>. In the young chick, it appears that taurine is a growth factor, which is intimately associated with bone development<sup>20</sup>. It has been suggested that it donates sulphate for esterification into chondroitin sulphate, but that this role, in the chick, is temporary during the early weeks of life. We may ask ourselves whether taurine has any of these functions in man or whether it has other activities as yet undiscovered.

### Effect of Vitamin E Deficiency on Ubiquinone Levels in Rat and Rabbit Liver

In a series of publications by Green and others<sup>1-3</sup> it was reported that the concentration of ubiquinone in animal tissues is depressed in tocopherol deficiency and that this vitamin (or a structurally related form) is specifically required for its maintenance or restoration. Investigations by Draper and others<sup>10-13</sup> indicated that all the well-characterized lesions observed in vitamin E deficiency are amenable to treatment with certain structurally unrelated synthetic antioxidants, notably *N,N'*-diphenyl-*p*-phenylenediamine (DPPD). These latter experiments led to the conclusion that functional displacement of tocopherol by DPPD occurs in metabolism and that the biological role of the vitamin is entirely attributable to its antioxidant properties. However, Green *et al.* reported that neither DPPD nor 'Santoquin' (1,2-dihydro-6-ethoxy-2,2,4-trimethylquinoline, another antioxidant which is active as a dietary substitute for tocopherols) was effective in maintaining ubiquinone levels<sup>4,7</sup> and they concluded that vitamin E has a specific non-antioxidant part in the metabolism of ubiquinone. In view of these reports we have investigated the effect of vitamin E deficiency and antioxidant treatment on ubiquinone concentrations in liver. It was chosen because it can be depleted of tocopherols and is known to show maximal change

No.

Three comparisons were made between vitamin E-deficient and control rats and one between normal and deficient rabbits. In experiments 1 and 2, control groups of 5-6 weanling female rats of the Sprague-Dawley strain were fed a basal vitamin E-deficient diet for 20 weeks. This diet contained the following ingredients (per cent): glucose 71.4, 'Labco' casein 20, salts 446 (ref. 14) 4, glycerol 2, vitamins in-glucose<sup>10</sup> 0.5, choline chloride 0.1, and 75 per cent methyl linoleate 2 (obtained from Nutritional Biochemicals Corporation, Cleveland, Ohio; remaining 25 per cent primarily methyl oleate). Vitamins A and D were added at levels of 100 and 5 I.U./g, respectively. Females raised to sexual maturity on this diet, and mated, have uniformly exhibited a resorption gestation unless given supplementary vitamin E<sup>10</sup>. The treated groups received a supplement of 0.5 mg DL- $\alpha$ -tocopheryl succinate or 0.25 mg DPPD/g of diet.

In Exp. 3, 15 weanling females were fed a diet except for replacement of th

('Skelly Solve F', b.p. 30°-60° C). In the case of the rabbit livers the bulk of the sterols was removed by suction filtration after crystallization at -15° C from petroleum ether and the residue was chromatographed on 1.6 cm x 10 cm columns. Ubiquinone was eluted in 4 per cent diethyl ether, recovered in ethanol and estimated by reduction with NaBH<sub>4</sub> at 275 m $\mu$ . The  $\Delta E_{1\text{ cm}}^{1\%}$  value of 142 for ubiquinone-50 was used throughout, as comparative values were of prime interest, although a small error accrues from its use owing to the presence of a high proportion of ubiquinone-45 in rat tissues. Recoveries of pure ubiquinone-50 applied to the column were essentially quantitative (96-102 per cent).

The results of the three rat experiments, shown in Table 1, fail to provide any evidence for a relationship between vitamin E status and the ubiquinone concentration in the liver. The data reveal wide ranges in ubiquinone levels within groups, but in none of the comparisons were there significant differences within experiments which can be attributed to a large variability in the ubiquinone levels. This has been cited by other workers as being associated with the degree of fatness. To illustrate the

were presumably attributable to some characteristic of the amino-acid basal diet used during the recovery period. The fact that the gross symptoms of the deficiency were alleviated by DPPD under these conditions confirms the conclusion reached previously that this compound is capable of direct metabolic substitution for tocopherols.

The results of this investigation are in agreement with the findings of Morton and Phillips<sup>24,25</sup>, Moore<sup>26</sup> and Phillips<sup>17</sup>, who reported that the ubiquinone content of the liver of vitamin E-deficient rats remained unchanged. It is difficult to account for the discordant results of Green and associates<sup>1-9</sup>, other than to point to the multiple dietary factors which obviously influence the ubiquinone level and to the difficulty of establishing significant treatment effects in the face of wide fluctuations within groups. In some instances the differences observed by these workers were relatively small and in certain cases the values for the deficient animals were the same as (or actually higher than) those for the normal controls. The magnitude of the differences observed in the present study

genetic uniqueness of Bence Jones proteins is related to the individual antigenic specificity of single immunizing proteins<sup>2</sup>. Another variable determining at least a part of the immunological difference between Bence Jones protein and normal unreduced  $\gamma$ -globulin is related to the unmasking of hidden antigenic determinants of *L* chains when they are either not incorporated into or cleaved from the parent  $\gamma$ -globulin molecule<sup>3</sup>. It has been suggested that certain potential antigenic sites of *L*-polypeptide chains are inaccessible in the intact  $\gamma$ -globulin molecule due to steric hindrance of adjacent *H* chain<sup>4</sup>.

The work recorded here was undertaken to investigate the possibility that there are additional antigenic differences between Bence Jones proteins and normal  $\gamma$ -globulin which are over and above those related to individual specificity and unmasking of hidden sites in the native intact molecule.

Bence Jones proteins were typed<sup>25</sup> and the results

Fig. 2. Immunodiffusion. Comparison of group 1 Bence Jones proteins and normal *L* chains. Well No. 1, Bence Jones protein 1-40; No. 2, Bence Jones protein 1-41; No. 3, Bence Jones protein 1-42; No. 4, normal *L* chains. Centre well contained a specific group 1 Bence Jones (1-40) antiserum absorbed with 5 mg of normal pooled  $\gamma$ -globulin and 7.5 mg of normal *L* chains.

sites, then the autologous myeloma proteins with presumably intact *L* chains should not contain the same degree of antigenic uniqueness as do the free *L* chains of the Bence Jones protein. The possibility exists that the *L* chains of the myeloma protein are sterically arranged so as to make available an ordinarily occult site. This would presuppose a different quaternary arrangement of *L* and *H* chains in a myeloma protein as contrasted to the arrangement in a normal  $\gamma$ -globulin molecule. This has not been described.

In order to clarify further these antigenic relationships, group specific Bence Jones antiserum (anti BJ1-40) was absorbed with lyophilized normal *L* chains (Fig. 2). Reactivity persisted against the immunizing protein (BJ1-40); prominent cross-reactivity was noted with two proteins of the same immunological group but from different patients. No reactivity was noted with normal *L* chains. In the unabsorbed state, this antiserum gave a strong precipitin line with the normal *L* chains. Similar findings were noted when *L* chains and group 2 Bence Jones proteins were compared, using an *L* chain absorbed group 2 Bence Jones antiserum. These findings further demonstrate the antigenic uniqueness of Bence Jones proteins when compared with normal *L* chains. This uniqueness is not related to individual specificity for the *L* chain absorbed antiserum cross-reacted with Bence Jones proteins of the same group from different patients. In addition, the antigenic uniqueness appeared not to be related to the hidden antigenic sites shared by normal *L* chains and Bence Jones proteins; for the absorbed antiserum failed to react with the free *L* chains. Thus Bence Jones proteins contain antigenic properties which are not overtly present in the isolated *L* chain polypeptide sub-units of normal  $\gamma$ -globulin.

Investigations by Kunkel, Mannik and Williams<sup>9</sup> suggest that purified human antibody of a given specificity can differ sufficiently in structure from other molecules of  $\gamma$ -globulin to impart a characteristic unique antigenicity. This uniqueness was localized to the papain split *S* fragment of the antibody molecule. It is thus possible that the distinctive antigenic characteristics of Bence Jones proteins may have apparent counterparts in the *L* chains of isolated antibodies.

These observations again raise the possibility that Bence Jones proteins are qualitatively abnormal, due to primary structural differences which are not present in the *L* chain sub-units of normal  $\gamma$ -globulin<sup>2</sup>. The fact that isolated antibodies possess antigenic uniqueness which may in part be related to the *L* chain component, however, lends

more weight to the possibility that Bence Jones proteins represent quantitative abnormalities in the sense that they are hypertrophied molecular components normally buried in the heterogeneous  $\gamma$ -globulin population.

### Labelled Tyrosinase from Labelled Substrate

It is well known that tyrosinase becomes inactivated when it oxidizes phenol or pyrocatechol but is much more stable towards substituted phenols and catechols, such as 4-5-dimethyl catechol<sup>1</sup>. We wish to report evidence which seems to support the view that this inactivation is due to the formation of a compound between the enzyme protein and the product of oxidation.

In the investigations reported here, 1-<sup>14</sup>C phenol (Radiochemical Centre, Amersham, Bucks, England) was used as substrate for mushroom tyrosinase (80 cresolase units per ml.). The enzyme was prepared according to the method of Frieden and Ottesen<sup>2</sup>, but omitting the final step of chromatography on diethyl amino ethyl cellulose.

Determination of levels of radioactivity were performed on a Nuclear Chicago planchette counter. The radioactive phenol was used as a solution of 0.5  $\mu$ mole per ml., which gave  $2 \times 10^5$  d.p.m./ml.

Reaction mixtures normally consisted of 0.5 ml. of a phenol solution, 1.0 ml. of 0.2 molar phosphate buffer (pH 7.0) sodium ascorbate and enzyme solution equivalent to 3 mg protein. Preliminary experiments demonstrated that when such a mixture was incubated at 25° C for 3-4 h, and the protein separated by vacuum dialysis or by boiling the reaction mixture, the protein was always radioactive. This radioactivity cannot be removed by washing successively with water, ether and acetone.

Enzyme which had been inactivated by heat did not become significantly radioactive when incubated with the reaction mixture and recovered as described here. In a typical experiment, the active enzyme gave 1,290 c.p.m. and the inactive preparation gave 90 c.p.m.

The possibility that the label was none the less produced by physical carry-over of radioactive material was finally removed by the following experiment. Identical flasks were prepared containing the usual reaction mixture, and were incubated for 2 h at 25° C. At the end of this time 10 mg of pyrocatechol was added to one of the flasks and incubation was continued for a further 5 h. Protein was then recovered in the usual way and plated out. The normal sample had a radioactivity of 2,049 c.p.m./mg; the catechol treated one had an activity of 1,612 c.p.m./mg. These results are more consistent with competition between the large excess of non-radioactive pyrocatechol and the minute amount of initially labelled material, for the remaining active sites than they are with dilution of carried-over catechol, since the latter process would be

expected to produce virtually non-radioactive protein with the great excess of non-radioactive catechol used here.

When a portion of the labelled protein was hydrolysed with 6 N hydrochloric acid, and the hydrolysate chromatographed with butanol:acetic acid:water (4:1:5) organic phase on Whatman No. 3 paper, examination of the chromatogram on the strip counter showed that all the radioactivity normally remained at the origin, although occasionally a small peak with an  $R_F$  of about 0.5 was observed. When a portion of the hydrolysate was freed of excess HCl, then shaken with 'Dowex 50' resin ( $H^+$  form), over 80 per cent of the radioactivity was retained on the resin, indicating the presence of a free basic group or groups on the radioactive molecule.

Hydrolysis of the radioactive protein with enzymes was next tested. Different portions were hydrolysed with trypsin and with pepsin, then chromatographed on paper using a solvent described by Waley and Watson<sup>3</sup>, namely, N-butanol/acetic acid/water/pyridine (30:6:24:70). This solvent also failed to move the radioactivity in an acid hydrolysate from the origin. The enzymic hydrolysates, however, gave a completely different picture. Each gave a rather broad diffuse area of material reacting with ninhydrin and a corresponding radioactive peak. These peaks were well removed from the origin. From similar chromatograms, not treated with ninhydrin, the radioactive areas were cut out and the soluble material was eluted with water. The solutions were clear and of a pale golden yellow colour. Both eluates were placed on Whatman No. 1 paper and chromatographed with butanol/acetic acid/water (4:1:5) (organic phase). The yellow-green colour of the spots of material on the paper was discharged completely by the acid chromatography solvent. The pepsin hydrolysate again gave a poorly defined peak. The tryptic hydrolysate gave a small radioactive peak at the origin, another small one just below the origin, and a large peak farther down the paper. This last peak was marked by the slow development of a brown colour on drying the paper. The large peak was eluted with water and hydrolysed with acid in the usual way. The hydrolysate was re-chromatographed with butanol/acetic acid/water solvent. As was to be expected, the rather inhomogeneous preparation yielded many amino-acids, and the radioactivity was present exclusively at the origin.

We have shown that when tyrosinase oxidizes radioactive phenol under conditions where the well-known substrate inactivation would normally occur, a radioactive protein can be obtained from the reaction mixture. The radioactivity cannot be removed by washing with water, acetone and ether in succession. Complete (acid) hydrolysis of the protein yields a radioactive material the chromatographic behaviour of which does not resemble that of phenol, pyrocatechol or o-benzoquinone, and which can be absorbed on to a weakly acidic ion-exchange resin—behaviour which one would not expect of phenol or its two derivatives. On mild (enzymatic) hydrolysis, however, radioactive components were obtained which are mobile in the chromatographic solvents tested.

While any consideration of the mechanisms involved must at this stage be purely speculative, it is reasonable to inquire whether reactions are already known to occur under physiological conditions which could account for these observations. We suggest that the newly formed quinone may, before leaving the active centre of the enzyme, undergo a Michael reaction with a free amino group of the enzyme, as in the cyclization of dopaquinone<sup>4,5</sup> during the conversion of tyrosine to melanin. The substrate thus becomes permanently attached to the active centre of the enzyme and prevents the enzyme from accepting and oxidizing other molecules of the catechol. This would account for the observation that homocatechol (4-methyl catechol) is less inhibiting than pyrocatechol, and the 4,5-dimethyl catechol is apparently devoid of

inhibitory action, since with the 4 and 5 positions blocked, the condensation would be completely impossible.

Attempts to investigate the mode of action of tyrosinase have so far been hampered by a lack of information about the nature of the active centre. The investigations described here offer a method of isolating, identifying, and investigating peptide fractions specifically derived from the active centre of the molecule.

We thank the National Institutes of Health (U.S. Public Health Service grant RG-8285) and the American Cancer Society for financial support of this project.

## PHYSIOLOGY

### Interactions between Active Sodium Transport and Active Amino-acid Transport in Isolated Rabbit Ileum

In previous publications dealing with ion transport across *in vitro* segments of rabbit terminal ileum, we have demonstrated that sodium is actively transported from mucosa to serosa and that the presence of an actively transported sugar in the mucosal solution increases the rate of active sodium transport by means of an interaction with the sugar transport *per se*<sup>1-3</sup>. In addition, we have presented a model for the sodium-sugar interaction<sup>3</sup> which is consistent with the demonstration of Bihler *et al.* that the entrance of actively transported sugars into the intestinal cell is dependent on sodium<sup>4</sup>. These findings, together with Csaky's observations that sodium is necessary for the active intestinal transport of amino-acids and pyrimidines, as well as active sugar transport<sup>5</sup>, led us to investigate the effect of actively transported amino-acids on sodium transport by rabbit ileum.

The short-circuit technique and other methods and procedures used in this investigation have been described previously<sup>1</sup>. The tissue was initially perfused with the buffer medium containing neither sugar nor amino-acid, and the amino-acid under examination was afterwards added to both the mucosal and serosal reservoirs simultaneously.

The effect of L-alanine on the short-circuit current ( $I_{sc}$ ) is shown in Fig. 1 (open circles). The increase in the  $I_{sc}$  (and the transmural potential difference) commences within 10 sec following the addition of the amino-acid, and the maximum level is usually achieved within 1-2 min. This increase is observed only if the amino-acid is added to the mucosal solution; addition to the serosal solution alone is ineffective. Furthermore,  $5 \times 10^{-4}$  M ouabain either prevents or diminishes the stimulation of the  $I_{sc}$  when added 10-15 min prior to the amino-acid and rapidly inhibits the  $I_{sc}$  when added after the amino-acid. This effect of ouabain is most marked when the glycoside is added to the serosal solution. As for the sodium-sugar interaction<sup>3</sup>, little or no effect of ouabain is observed when it is added to the mucosal solution alone.

Also shown in Fig. 1 (closed circles) are the results of a typical experiment in which the perfusion medium was initially sodium-free as the result of replacement of sodium with potassium. In the absence of sodium the  $I_{sc}$  does not differ significantly from zero and no effect is observed following the addition of L-alanine. The sub-

Fig. 1. The effect of 10 mM L-alanine on the  $I_{sc}$  in the presence of 142 mM sodium (open circles) and in the presence of a sodium-free medium (closed circles). Following the addition of alanine, the medium which was initially sodium-free was diluted with the 142 mM sodium medium to give final sodium concentrations of 72 mM and 105 mM. The times of these dilutions are indicated by arrows.

sequent addition of sodium to the medium (arrows) results in an immediate increase in the  $I_{sc}$  and the levels achieved approach those which would be predicted by a linear relationship between the  $I_{sc}$  and the sodium concentration of the medium<sup>3</sup>.

We have previously demonstrated that there is good agreement between the  $I_{sc}$  and the rate of active sodium transport by terminal rabbit ileum both in the presence and absence of actively transported sugars<sup>1,2</sup>. In Table 1 are shown the mucosa-to-serosa ( $\Phi_{ms}^{Na}$ ), serosa-to-mucosa ( $\Phi_{sm}^{Na}$ ) and net ( $\Phi_{net}^{Na}$ ) fluxes of sodium and the average  $I_{sc}$  in the presence and absence of L-alanine (10 mM). The agreement between  $\Phi_{net}^{Na}$  and the  $I_{sc}$  supports the conclusion that the increase in the  $I_{sc}$  following the addition of L-alanine may be attributed to an increased rate of active transport of sodium. Recently, Esposito *et al.*<sup>6</sup> have demonstrated that the rate of sodium transport by everted sacs of rat intestine is increased by both glucose and amino-acids in complete agreement with our findings.

Table 1. EFFECT OF L-ALANINE ON SODIUM FLUXES IN RABBIT ILEUM\*

† Electrolyte medium containing neither sugar nor amino-acid.

The relationship between the magnitude of the increase in the  $I_{sc}$  ( $\Delta I_{sc}$ ) and the concentration of L-alanine added to the perfusion medium is shown in Fig. 2. The curve is that predicted by a least-squares fit of the data plotted according to the method of Lineweaver and Burk<sup>7</sup> and indicates that the relationship between the  $\Delta I_{sc}$  and the concentration of L-alanine is consistent with Michaelis-Menten kinetics. The concentration of L-alanine which

elicits a half-maximal stimulation of the  $I_{sc}$  is 4.5 mM. Finch and Hird<sup>8</sup> have demonstrated that the uptake of L-alanine by rat intestine conforms to Michaelis-Menten kinetics and that the half-maximal rate of uptake is observed in the presence of 5 mM alanine. The similarities between our results and the kinetics of alanine transport reported here suggest that, barring major species differences with respect to the rate of alanine transport, there is a stoichiometric relationship between this rate and the increased rate of active transport of sodium.

The results described here are not limited to L-alanine. Significant stimulation of the  $I_{sc}$  has been observed following the addition of glycine, L-methionine,  $\alpha$ -amino-iso-butyric acid, L-lysine, L-glutamate (potassium salt), L-glutamine, as well as D-methionine, D-alanine and D-glutamate (potassium salt). Since we have not measured sodium fluxes in the presence of these amino-acids, the significance of these findings is uncertain. It is not improbable however that, as in the instance of L-alanine, the increase in the  $I_{sc}$ , particularly in the presence of neutral amino-acids, is attributable to an increase in active transport of sodium. Since the active transport of anionic or cationic amino-acids would by itself influence the  $I_{sc}$ , that portion of the  $\Delta I_{sc}$  which may be the result of an increased rate of transport of sodium cannot be defined in the absence of simultaneous determinations of both the amino-acid and sodium fluxes.

Finally, we have previously reported that once the  $I_{sc}$  has been maximally stimulated by an actively transported sugar the subsequent addition of another actively transported sugar does not elicit a further increase in the  $I_{sc}$ . This finding was interpreted as being consistent with the presence of a single, saturable carrier mechanism which is responsible for active intestinal sugar transport<sup>3</sup>. When, on the other hand, the  $I_{sc}$  has been maximally stimulated by the addition of either glucose or 3-O-methyl-glucose the subsequent addition of either L-alanine, L-lysine or L-glutamate results in a further large increase in the  $I_{sc}$ . This additive effect is also observed if the sequence of addition is reversed (that is, amino-acid, then sugar). Furthermore, the magnitude of the second rise in the  $I_{sc}$  usually approaches that which would be expected to follow the addition of the sugar or amino-acid alone. These findings are consistent with the evidence that the active transport of amino-acids and sugars are mediated by separate and parallel carrier mechanisms<sup>9</sup>, and suggest that the operation of each of these mechanisms results in an increased rate of entrance of sodium from the mucosal solution into the intestinal cell.

In recent years the finding that sodium is required for the active transport of sugars and/or amino-acids has been extended to many tissues other than mammalian intestine, for example, kidney slices<sup>11,10</sup>, leucocytes<sup>12</sup>

Fig. 2. The relationship between the concentration of L-alanine in the perfusion medium and the increase in the  $I_{sc}$  ( $\Delta I_{sc}$ ).

a marine pseudomonad<sup>13</sup>, Ehrlich ascites tumour cells<sup>14</sup>, pigeon erythrocytes<sup>15</sup>, striated muscle<sup>16</sup> and thymus nuclei<sup>17</sup>. Our findings that the active intestinal transport of sugars and amino-acids not only requires sodium but also brings about an increased rate of trans-mural sodium transport suggests that the role of sodium is not simply that of an activator of these transport processes. Instead, it is suggested that the active transport of both sugars and amino-acids is mediated by a ternary sodium-sugar or amino-acid-carrier complex and is dependent on the ability of the cell to maintain an intracellular sodium concentration lower than that in the surrounding medium. The inhibitory effect of ouabain on these sodium-dependent transport processes<sup>8,11,16</sup> may be solely the result of its inhibition of the active sodium extrusion mechanism which is responsible for the maintenance of the sodium concentration gradient. A more detailed description of this hypothetical model has been published<sup>9</sup>, and Vidaver has recently suggested an analogous model consistent with his findings concerning the sodium-dependence of glycine uptake by pigeon erythrocytes<sup>18</sup>.

### Inhibitory Synapses and Inflammation

B. RENSHAW<sup>1</sup> has shown that part of impulses from the motoneurons is not directed to the muscles; it spreads by way of a branch of the motoneurone axon through an inhibitory interneurone and then returns to inhibitory synapses covering the same motoneurone which originally evoked the impulse. Now it is known that nearly all neurones at all levels of the central nervous system possess a self-inhibitory mechanism of that kind.

J. C. Eccles *et al.*<sup>2</sup> have shown that strychnine and tetanotoxin block the inhibitory synapses and therefore increase the spinal polysynaptic reflexes.

Most diseases are revealed by inflammatory processes. Therefore it seems to be very significant that, as shown by us, the inhibitory synapses are also of great importance

Fig. 1. Mono- and poly-synaptic reflexes from the damaged leg (3) are larger than the mono- and poly-synaptic reflexes from the undamaged paw (1). The injection of strychnine evokes a sharper increase of poly-synaptic reflexes from the damaged leg (4) than from the undamaged leg (2). The stimuli supernormal for the I group of fibres were applied to n. peroneus comm.

Fig. 2. Primary responses of the I sensory motor area from the damaged leg (2) are larger than from undamaged leg (1). The injection of strychnine evokes a sharper increase of the primary response from the damaged leg (4) than from the undamaged leg (3). Besides this a secondary response appears from the damaged leg (4). Each record has been formed by super-position of 5 traces. The white points mark the moment of stimulation. The stimulus (350 mV) is applied to n. peroneus superficiales

for the reactions evoked by the impulses from inflamed tissues. In our experiments the inflammation was evoked in one of the hind paws of a cat by means of cutaneous injection of turpentine (0.2–0.3 c.c.). Some hours or days later the strychnine-nitrate (0.05 mg/kg) was injected intravenously into the same animal. The spinal reflexes were evoked by stimulation of the n. peroneus comm. The strychnine acts on the reflexes of the animals with a damaged paw in the same way as it does on reflexes of healthy animals, but there is a very important peculiarity. On the side of the damaged leg the polysynaptic reflexes increase by 100–200 per cent as compared with the side of the undamaged one (Fig. 1).

A similar effect was established by investigation of the evoked potential of the brain. The injection of strychnine

increases the evoked potential both in the cortex (I and II somatosensory zones) and in the specific nucleus of thalamus (*VPL*), being much sharper in the hemisphere contralateral to the damaged leg than in the ipsilateral one (Fig. 2).

On the basis of these experiments it is obvious that the amount of neurones—at the level of spinal cord or higher, in the sub-cortex or cortex involved in the pathological reaction—depends on the activity of the inhibitory synapses. The blocking of inhibitory synapses has shown very clearly that in this case many more neurones could be involved in the pathological reaction and therefore it could become excessive.

In our previous experiments<sup>3</sup> it was shown that the compensation of disfunction of some damaged organs depended on the nervous system. It is possible that inhibitory synapses are the basis of the compensation.

### Development of Acetylcholinesterase Activity at Muscle-tendon Junctions

In vertebrate skeletal muscles, besides a strong acetylcholinesterase activity at motor end-plates, a weaker but well-defined activity is found at muscle-tendon junctions<sup>1,2</sup>. Whereas the functional role of acetylcholinesterase at the end-plates seems to be well established, both the origin and function of the enzyme at muscle-tendon junctions remain obscure. The question was often raised whether the concentration of the enzyme at these sites could not be in some relation to the motor or sensory innervation of the muscle. However, acetylcholinesterase activity at muscle-tendon junctions appears to be unaltered after nerve section in adult animals<sup>3</sup>. On the other hand, in tissue culture no concentration of the enzyme develops either in the middle part or at the ends of muscle fibres<sup>4</sup>, and it has been suggested that this might be due to the absence of nerves<sup>5</sup>.

It seemed, therefore, of interest to test the possible influence of innervation, either motor or sensory, on acetylcholinesterase activity at muscle-tendon junctions in developing muscles.

The formation of acetylcholinesterase-active sites was examined histochemically<sup>6</sup> in the calf muscles of the rat during development. Traces of acetylcholinesterase activity were found at the ends of some muscles already in foetuses before birth. In new-born rats acetylcholinesterase activity is still very low at muscle-tendon junctions, whereas at the end-plate region the activity is fairly strong and well localized.

To determine the role of innervation in further development muscles were denervated at the early stage of incipient formation of muscle-tendon cholinesterase. The sciatic nerve was sectioned in new-born rats and acetylcholinesterase activity was examined in denervated calf muscles, mainly in the soleus muscle, from 3 days–1 month after the operation.

After the nerve section at birth, no acetylcholinesterase activity was formed at muscle-tendon junctions in denervated muscles. The small amount of acetylcholinesterase present at muscle ends at birth disappeared within 3–7 days and the fibre ends remained devoid of

Fig. 1. Above, acetylcholinesterase activity at muscle-tendon junctions of the soleus muscle in normal rat three weeks old; below, absence of acetylcholinesterase activity at muscle-tendon junctions in the soleus muscle three weeks after motor denervation in litter-mate rat with spinal cord removed at birth, from the level  $L_1$  downward. Note richly branched cholinesterase-active sensory fibres. Method of Koelle and Friedenwald, slightly modified<sup>6</sup>. Frozen sections 25  $\mu$ , incubation 2 h at pH 6.2

the enzyme activity throughout the investigated period. No acetylcholinesterase activity could be detected at muscle-tendon junctions even when incubation with the substrate was prolonged to 2, 4 and 24 h. In the end-plate region, acetylcholinesterase activity decreased rapidly after denervation, and further development of the end-plates was arrested, as has been already described<sup>7</sup>. One month after denervation, acetylcholinesterase in the soleus muscle was scarcely detectable even at the end-plate region.

In the control muscles, acetylcholinesterase activity increased rapidly after birth, and within a few days the intensity of staining and shape of the active sites were similar to those of adult animals.

In the rat, motor nerve fibres supply the region of end-plates localized in the central parts of muscle fibres. Outside this region only polar zones of intrafusal fibres in muscle-spindles receive motor innervation. Some of the sensory fibres, however, reach the ends of the muscle fibres and innervate tendon organs or form free endings at the tendon. It was therefore important to find out whether the disappearance of acetylcholinesterase at muscle-tendon junctions was due to the loss of remote motor endings or of the nearby sensory innervation, or both.

To check these possibilities, another series of experiments was carried out in which the spinal cord was removed in new-born rats from the level  $L_1$  downward. This operation completely eliminates the motor innervation of muscles in hind limbs, whereas their sensory nerve

supply remains unaffected. After such motor denervation, acetylcholinesterase disappeared from muscle-tendon junctions as it did after the section of the nerve (Fig. 1). Only tendon organs frequently found in this region exhibited a strong cholinesterase activity, and richly branched acetylcholinesterase-active sensory fibres were well stained.

Although the mechanism leading to the accumulation of acetylcholinesterase at the muscle-tendon junction remains unknown, the decisive role of motor innervation in its development seems firmly established by these experiments.

I thank Prof. L. Lubińska for her valuable advice, Mrs. M. Sobotková for her assistance, and Mr. J. Kubec for taking the photographs.

### Antagonism between $\text{Na}^+$ and $\text{Ca}^{2+}$ at the Neuromuscular Junction

THE quantity of transmitter released from presynaptic nerve terminals is in part determined by the amplitude of the action potential<sup>1,2</sup> invading the nerve terminals, and by the amount of a specific calcium-compound available at some strategic site<sup>3</sup>. Large reductions in external  $\text{Na}^+$  concentration, however, which would be expected to reduce the size of the propagated action potential<sup>4</sup>, do not greatly alter the output of acetylcholine at cholinergic nerve endings<sup>5,6</sup>. This might be explained if it were supposed that the reduction in  $\text{Na}^+$  concentration also increased the amount of available calcium-compound at the strategic site;  $\text{Na}^+$  deficient solutions might then maintain the release of transmitter in spite of the reduction of the amplitude of the action potential. On this hypothesis a  $\text{Na}^+$  deficient solution might be expected to increase the amount of transmitter released when the calcium concentration is low. Such an increase in transmitter release has been found in the experiments reported below.

By methods similar to those described by Fatt and Katz<sup>7</sup> intracellular records were made of evoked and spontaneous end-plate potentials from frog sartorii bathed in solutions which contained 0.23 mM  $\text{Ca}^{2+}$ , 2.0 mM  $\text{K}^+$  and various concentrations of  $\text{Na}^+$ ; tonicity being maintained by the addition of sucrose. The microelectrode was inserted into the end-plate region of a muscle fibre and approximately 100 evoked end-plate potentials followed by 50–100 spontaneous end-plate potentials were recorded. The microelectrode was left undisturbed while the concentration of  $\text{Na}^+$  in the bath was changed and allowed to equilibrate, after which the records were repeated. The mean number of 'quanta' of acetylcholine released per nerve impulse was calculated in each of the  $\text{Na}^+$  concentrations from the ratio of the mean evoked response to the mean spontaneous end-plate potential amplitude<sup>3</sup>. The amplitudes of the end-plate potentials were corrected for 'non-linear' summation<sup>8</sup>, the equilibrium potential for acetylcholine<sup>9</sup> being taken to be 50.1 and 57.3 mV in 23.1 and 38.5 mM  $\text{Na}^+$  respectively.

Records from a typical experiment are illustrated in Fig. 1. Evoked end-plate potentials from the end plate while bathed in normal  $\text{Na}^+$  (115.6 mM) and one-eighth normal  $\text{Ca}^{2+}$  (0.23 mM) are shown in Fig. 1A, and the spontaneous end-plate potentials in Fig. 1C. When the solution in the bath was changed to one-third normal

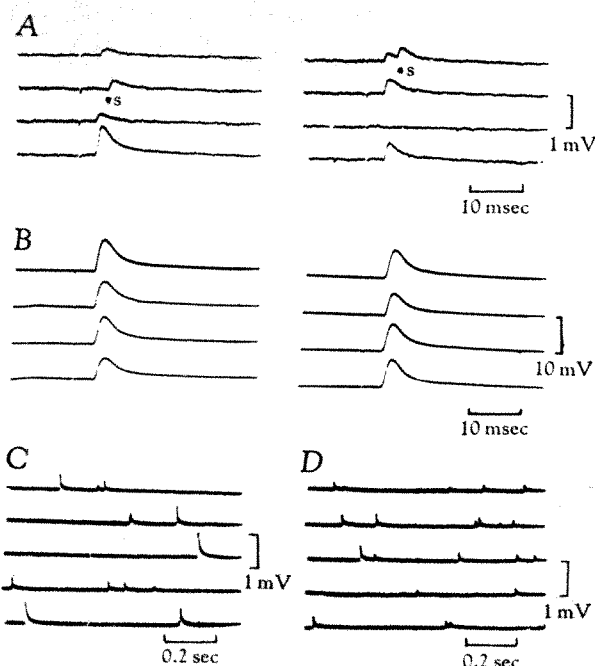

Fig. 1. Effect of reducing the concentration of  $\text{Na}^+$  on the evoked and spontaneous end-plate potential in 0.23 mM  $\text{Ca}^{2+}$ . A, selection of evoked end-plate potentials recorded in normal  $\text{Na}^+$ . The mean quantal content per nerve impulse was 0.9. Two of the responses were 'failures'; s indicates probable spontaneous end-plate potentials. B, responses recorded at the same end-plate in one-third normal  $\text{Na}^+$ . Note change in gain. The mean quantal content was 36. Spontaneous end-plate potentials recorded in normal  $\text{Na}^+$  (C) and in one-third normal  $\text{Na}^+$  (D).

$\text{Na}^+$  (38.5 mM) the evoked end-plate potentials were increased in amplitude (Fig. 1B), although the mean amplitude of the spontaneous end-plate potentials was reduced (Fig. 1D). In solutions containing one-fifth normal  $\text{Na}^+$  (23.1 mM) the amplitude of the end-plate potential was often sufficiently large to exceed the threshold required to initiate an action potential.

In Table 1 the results of 10 experiments show the marked increase of the number of quanta released per nerve impulse in low  $\text{Ca}^{2+}$  medium when the normal  $\text{Na}^+$  was replaced by  $\text{Na}^+$  deficient solutions. Conversely, there was a marked reduction when a  $\text{Na}^+$  deficient solution was replaced by normal  $\text{Na}^+$ .

These results suggest there is at the neuromuscular junction an antagonism between  $\text{Na}^+$  and  $\text{Ca}^{2+}$ , perhaps similar to that between  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$  (ref. 10). An antagonism

Table 1. RESULTS OF TEN EXPERIMENTS SHOWING THE EFFECT OF CHANGING THE  $\text{Na}^+$  CONCENTRATION ON THE MEAN NUMBER OF QUANTA RELEASED PER NERVE IMPULSE

The  $\text{Ca}^{2+}$  concentration was kept constant at 0.23 mM. The normal  $\text{Na}^+$  concentration ( $\text{Na}^+ = 1$ ) was 115.6 mM

Experiment No.	Relative $\text{Na}^+$ concentration	Mean amplitude of corrected end-plate potentials (mV) ( $\pm$ S.D.)	Mean amplitude of spontaneous end-plate potentials (mV) ( $\pm$ S.D.)	Mean No. of quanta released per nerve impulse and fiducial limit

### Intracellular Postsynaptic Potentials in the Somatosensory Cortex of the Cat

CELLULAR activity in the somatosensory cerebral cortex has been investigated in detail with extracellular recording. Excitatory phenomena have dominated the findings in these experiments although inhibitory actions, mostly as 'surround inhibition', have been reported<sup>1-3</sup>. Since inhibition is abundant in the relay nuclei of the specific projection system<sup>4-6</sup> it has generally been assumed that the inhibition of cortical cells reflects inhibitory actions at sub-cortical level. The present results show, however, that powerful inhibitory potentials are generated in many cortical cells.

The experiments were performed on cats anaesthetized with 'Nembutal'. The intracellular activity was recorded from cells in the hindlimb area of  $S_1$  with glass micropipettes filled with 3 M potassium chloride or 2 M potassium citrate. Cortical movements were largely reduced by using a closed chamber system modified after Davies<sup>7</sup>.

In one type of experiment the dorsal part of the spinal cord was transected at the level of Th 12. The dorsal columns (DC), and the dorsal part of the lateral funiculus (DLF) contralateral to the investigated hemisphere, were dissected for electrical stimulation in ascending direction. In another group of experiments the cortical activity was investigated in preparations with intact spinal pathways and the animal was stimulated with single electrical shocks to the skin or with adequate stimulation of the skin. In this type of experiment some of the cortical cells could be classified with regard to the modality of the peripheral stimulus. In both types of preparations more than 100 cells were investigated intracellularly with regard to the postsynaptic potentials evoked by an afferent stimulation. The time of observation varied between one and 30 min. The mean resting membrane potential was 45 mV.

The most striking feature in the postsynaptic activity evoked by an afferent stimulus was a long-lasting hyperpolarization which was found in 80 per cent of the cells. Most commonly the inhibitory postsynaptic potential (IPSP) appeared initially, but in other cells the inhibition was post-excitatory. In the remaining 20 per cent of the cells only depolarization could be elicited. These principal types of synaptic actions were found in both types of preparations.

In cells being only hyperpolarized in response to stimulation the afferent volley elicited an IPSP with a steep rising phase and a slow decline (Fig. 1A). The mean latency was 9.8 msec and the mean duration 65 msec when the stimulus was applied to the dissected spinal fascicles at Th 10. In other cells the afferent stimulation elicited a depolarization followed by a prolonged hyperpolarization. The initial excitation had a mean latency of 9 msec when the stimulus was applied at Th 10. The duration of the depolarization as well as of

Fig. 1. Intracellular (intrac.) and extracellular (extrac.) records from the hindlimb area of  $S_1$  in response to a single afferent volley. Records A, B, D and F show the response to electrical stimulation at Th 10 of the dissected dorsal columns. Records C and E were obtained in a preparation with intact spinal cord. A, IPSP, resting membrane potential 63 mV. B, EPSP with postexcitatory hyperpolarization, resting membrane potential 70 mV. C, Hyperpolarization with depolarizing unitary potentials in response to tactile stimulation in a small skin area on the contralateral hindlimb, resting membrane potential 42 mV. D, EPSP, resting membrane potential 32 mV. E, Rhythmic inhibitory postsynaptic potentials elicited by an electrical shock to the contralateral hindlimb, resting membrane potential 63 mV. F, Rhythmic excitatory postsynaptic potentials elicited by a single electrical shock to the DC at Th 10, resting membrane potential 56 mV.

the hyperpolarization varied considerably between different cells. In one group of cells the excitatory effect had a similar duration to that in the cells showing only depolarization. In such cells postexcitatory hyperpolarization usually lasted less than 100 msec (Fig. 1B). In many cells the depolarization was very short, lasting only 5-10 msec and followed by a hyperpolarization, frequently with a duration of 100-150 msec. In the preparations with intact spinal cord some of these cells were identified as cells quickly adapting in response to bending hairs in a small contralateral receptive field. One group of cells responded to afferent stimulation only with an excitatory postsynaptic potential (EPSP). The membrane potential returned gradually to its resting value and there was no hyperpolarization (Fig. 1D). The mean latency of the EPSP was 9 msec and the mean duration 50 msec when the stimulus was applied at Th 10.

In the preparations with dissected spinal fascicles an EPSP or IPSP could be evoked in many cortical cells by an electrical shock to the DC as well as to the DLF. Other cells responded only to stimulation of the DC and in a few cells an EPSP was obtained only from the DLF.

In connexion with the synaptic potentials, unitary potentials were frequently observed. The amplitude of these potentials was usually one or a few millivolts. In most cells this activity appeared during the depolarization, but in some cells it appeared during the hyperpolarization (Fig. 1C). In some cells with a low membrane potential these unitary potentials were probably abortive action potentials and in these cells the spike arose from a primary depolarization. Most cells, however, had a constant resting membrane potential of 60-70 mV for many minutes and showed no injury discharge at impalement. Some of the cells could suddenly discharge with spikes of high amplitude which probably represented ordinary action potentials. It seems likely that the small unitary

potentials in these cells represent either the bombardment on the cell from excitatory presynaptic terminals or dendritic spike potentials not exciting the soma.

Regardless of the type of activation the initial response was frequently followed by repetitive after-discharges lasting for about 500 msec in response to one afferent stimulation. In other cells the initial response did not appear and there were only the late rhythmical discharges. Usually the following membrane potential oscillations were very similar to the initial response and consisted of rhythmical hyperpolarizations (Fig. 1E) or depolarizations (Fig. 1F). The interval between the initial response and the first after-discharge was about 100 msec, and the interval between the after-discharges was 60–80 msec. The rhythmical depolarizations probably represent the thalamic after-discharges now known to be due to post-inhibitory hyperexcitability in thalamic cells<sup>4</sup>. The rhythmical inhibitory potentials may have a similar origin or they may be due to a cortical event.

It is still too early to evaluate the relative significance of the inhibitory and excitatory activities evoked from the specific projection pathways in cells of the somatosensory cortex. It seems to be a reasonable working hypothesis that the inhibition eliminates stray excitation and thus subserves spatial discrimination.

## HAEMATOLOGY

### Erythrocytic Enzymes of Various Animal Species

ENZYMES involved in the reduction of triphosphopyridine nucleotide (TPN) have been reported to be of primary importance in the resistance of erythrocytes to drug-induced hemolytic conditions<sup>1</sup>. A hereditary defect in man associated with erythrocytes sensitive to drugs (primaquine) has been described in which there is a deficiency of hexose monophosphate pathway enzymes in the erythrocytes. Evidence of a susceptibility to drug-induced hemolysis of erythrocytes has also been reported in the dog<sup>2</sup>.

The sheep and goat have been reported to be completely void of erythrocyte glucose-6-phosphate dehydrogenase (G-6-PD) activity by several investigators<sup>3,4</sup>, while others have reported very low activity<sup>5,6</sup>. There is, however, no reported evidence of increased drug sensitivity associated with these low or absent enzyme concentrations in sheep erythrocytes. Reports on the presence of G-6-PD in the erythrocyte of the pig<sup>5,7</sup> are also conflicting. The erythrocytes of most other domestic animals have been shown to contain about the same amounts of G-6-PD activity as do human erythrocytes<sup>5</sup>. Because of these conflicting reports concerning the pentose phosphate pathway enzymes and the fact that erythrocyte glucose metabolism can proceed alternatively via glycolysis to lactate the present study was undertaken to define the status of G-6-PD in relation to the glycolytic enzymes in several domestic animals.

All blood samples were collected from mature animals by venipuncture into heparinized tubes. Haemoglobin concentration was measured by the cyan-methaemoglobin method, and packed cell volumes (PCV) were obtained by the micro-haematocrit method. Haemolysates were pre-

pared from erythrocytes which had been previously washed with physiological saline, by addition of 10 or 20 volumes of distilled water. Haemoglobin concentration was determined in all haemolysates which were used for determination of enzyme activity. All enzyme measurements were conducted at 25° using a Gilford Model 2000 Multiple Absorbance Recorder which permitted the measurement of very small changes in absorbancy at 340 mμ in the presence of high levels of haemoglobin. Therefore, the separation of haemoglobin before the assay was not necessary as in experiments previously reported<sup>8</sup>. All enzyme activities are reported as μmoles of pyridine nucleotide reduced or oxidized per g of haemoglobin per h. Glucose-6-phosphate dehydrogenase was measured by a modification of the method of Glock and McLean<sup>9</sup>. Phosphohexoseisomerase was estimated by using fructose-6-phosphate, purified glucose-6-phosphate dehydrogenase, and TPN<sup>+</sup>. Aldolase and glyceraldehyde-3-phosphate dehydrogenase were assayed using DPN, arsenate, and fructose-1,6-diphosphate; in the case of the aldolase assay excess glyceraldehyde-3-phosphate dehydrogenase was added, and in the assay of the glyceraldehyde-3-phosphate dehydrogenase excess aldolase was added; in both cases DPNH production was measured. Lactate dehydrogenase was measured by a modification of a method described earlier<sup>10</sup>. All substrates, coenzymes, and enzymes were obtained from Sigma Chemical Company, St. Louis, Mo., U.S.A.

Table 1

	Species

G-6-PD/ALD						
ratio	0.66	4.93	1.23	3.13	2.12	5.04

Enzyme activities are reported as μmole of pyridine nucleotide reduced or oxidized per g of haemoglobin per hour

The results of these investigations are reported in Table 1 and indicate that G-6-PD activity is present in the erythrocytes of all species examined. The activity found in sheep erythrocytes was of such a low magnitude, however, that further studies were performed to determine whether the slow reduction of TPN was actually linked to G-6-PD. An ammonium sulphate fractionation of this enzyme resulted in a 12-fold increase in specific activity of the enzyme from sheep and a 7-fold increase from cattle from these findings. We would conclude that G-6-PD activity is present, though in small amount, in contrast to some earlier reports, in the erythrocytes of sheep. Since more enzyme could be used from these preparations, due to considerable haemoglobin removal, a 60-fold increase in activity per cuvette could be achieved and left no doubt as to the occurrence of G-6-PD in the erythrocytes of this species. The reported absence of activity may have been due either to the very low levels of enzyme present or to inefficient hydrogen acceptance by the dyes employed. The latter has been reported to occur in investigations with monkey erythrocytes<sup>11</sup>. The G-6-PD levels found in the other species are similar to the values reported by other investigators.

Of the glycolytic enzymes assayed, aldolase activity was the lowest and thus may be the rate-limiting enzyme of the glycolytic pathway. This is in agreement with other observations on human erythrocytes<sup>12</sup>. Glycolytic enzyme activities in the sheep, pig, dog and monkey in decreasing order were lactic dehydrogenase > phosphohexose isomerase > glyceraldehyde-3-phosphate dehydrogenase. This order does not apply to horse and cow erythrocytes. The G-6-PD/aldolase ratio suggests that among the various species there may be a marked variation in the relative importance of the glycolytic and pentose

pathways. Differences in the biochemical behaviour of the erythrocytes of various species may represent adaptations to different physiological needs and therefore may account for species differences in susceptibility to various haemolytic agents (such as copper poisoning in sheep). The presence of an inherited erythrocytic enzyme deficiency in animals is also possible and could similarly account for the unexplained susceptibility of individual animals to certain drugs. For example, the susceptibility to toxic effects of phenothiazine presents a peculiar dose problem because there is an extremely wide variation in the response of individuals of the same species to similar doses of the drug. Individual horses may also suffer a haemolytic crisis not shown by other animals<sup>13</sup>.

## IMMUNOLOGY

### Specificity of Guinea-pig Antibodies and Delayed Hypersensitivity

THE pioneering work of Landsteiner<sup>1</sup> on the serological reactions of rabbit anti-hapten antibodies showed that these antibodies were highly specific for the simple haptenic molecule. Thus, antibody-hapten interactions usually depend on the chemical nature of the hapten rather than on that of the protein carrier to which the hapten is attached. While this hapten-directed specificity appears to be the general rule, it has been pointed out repeatedly in the past (most notably by Mutsaers and Gregoire<sup>2</sup> and Haurowitz<sup>3</sup>) that the rabbit may also produce antibodies the specificity of which extends to the hapten-protein linkage and may even encompass nearby portions of the protein carrier itself.

The immunological specificity of the delayed hypersensitivity response in guinea-pigs stands in direct contrast to the specificity of rabbit antibodies. As many authors have shown<sup>4-6</sup>, the elicitation of the delayed hypersensitivity reaction appears to involve an obligatory participation of the carrier protein as well as the haptenic moiety. Based on this specificity difference, it has been suggested that the delayed response recognizes and requires an appreciably larger antigenic determinant than does conventional circulating antibody. These specificity differences have also been cited in support of the suggestion that delayed hypersensitivity is unrelated to other forms of immunological response.

\* Since the results cited above were based on experiments involving two different animal species, it was of interest to examine the guinea-pig antibodies, frequently

detectable in the circulation a few days after the development of delayed hypersensitivity to a single injection of a hapten-protein conjugate. The specificity of these antibodies was compared with that of the delayed reaction on one hand and of rabbit anti-hapten antibodies on the other.

The haptens used for our experiments were *p*-amino-benzoate and *p*-nitroaniline, coupled to purified guinea-pig albumin (GpA) for immunization and testing and to crystalline hen ovalbumin ('Oval') for cross-testing. The haptens were attached to the carriers either by diazonium coupling forming 'azo' links mainly with the tyrosine and histidine residues, or by reacting their isocyanate or isothiocyanate derivatives with the ε-amino groups of the lysine residues of proteins to form respectively the carbamido or thiocarbamido conjugates.

Guinea-pigs were immunized with 10 μg of *p*-benzoate thiocarbamido-GpA or *p*-nitrobenzene carbamido-GpA, or with 100 μg of *p*-benzoate azo-GpA or *p*-nitrobenzene azo-GpA, injected intradermally in a complete Freund's adjuvant. The animals were bled daily from the 7th day after immunization. The sera obtained in this way were tested for antibodies by passive cutaneous anaphylaxis<sup>7</sup> using homologous antigens and also antigens heterologous with respect to either the hapten-protein linkage (azo vs. thiocarbamido) or to the carrier protein (GpA vs. 'Oval'). Control animals not employed in the antibody studies were skin-tested with 10 μg doses of the several antigens to assess the development of delayed sensitivity and its specificity.

In conformity with earlier observations, guinea-pigs sensitized in this manner developed typical delayed skin reactivity within 6-8 days after immunization. In every instance, the specificity was such that no cross-reactions were observed with either the homologous hapten on the different carrier protein, or with the homologous hapten linked differently to the same carrier protein employed for sensitization.

In each animal studied, the earliest antibody to appear in the circulation (usually on the 10th-14th day after immunization) was both carrier- and link-specific. Within 1-7 days thereafter, depending on individual variation, this was followed by the appearance of antibody which cross-reacted with antigens containing a heterologous link or carrier.

The variation in response among the different guinea-pigs was reflected not only in the time of appearance of cross-reacting antibodies but, curiously, in the temporal order of this appearance. The results outlined in Tables 1-3 are from individual animals selected to illustrate this point. In Table 1 are data from an animal which produced carrier- and link-specific antibody for only one day before cross-reaction for the heterologous link developed. One week later, antibody able to cross-react with the unrelated carrier protein appeared in the circulation. Table 2 shows an animal that formed very specific antibody for a full week before cross-reacting activity appeared first for the heterologous linkage and then for the heterologous carrier protein. On the other hand, the animal described in Table 3 developed a cross-reaction to the unrelated carrier protein some days before it formed antibody able to cross-react with the unrelated linkage. There appeared to be no consistent relationship between the order of decrease in antibody specificity and the type of hapten or linkage employed for immunization.

Preliminary experiments based on the known susceptibility of macroglobulins to reducing agents<sup>8</sup> suggest that the earliest antibody is mainly of the 19 S macroglobulin type. Treatment of some of the sera with 0.05 M 2-mercaptoethanol (buffered at pH 7.2) for 30 min at 37° C resulted in inactivation of the earliest, carrier- and link-specific antibody while affecting little or not at all the later, cross-reacting antibodies.

Some years ago we presented evidence<sup>9</sup> that the delayed hypersensitive guinea-pig might form anti-hapten anti-

bodies with a specificity extending to the haptenic linkage and presumably also to the amino-acid to which the hapten is attached. The present data extend this observation and indicate that antibody with even more stringent requirements for antigen may be formed under similar circumstances. The specificity of this antibody involves a determinant large enough to include not only the hapten, but also a portion of the carrier protein molecule adjacent to it. Neither hapten nor carrier protein alone appears to provide sufficient interaction energy to mediate the passive cutaneous anaphylactic reaction. Such a specificity is typical of delayed hypersensitivity, and suggests that antibody formation and delayed hypersensitivity are not separable on the basis of specificity considerations alone. The demonstration that the carrier protein also partakes in the specificity of immunological tolerance<sup>9</sup> and of the anamnestic antibody response to hapten-protein conjugates<sup>10,11</sup> further emphasizes this point.

## PATHOLOGY

### Simultaneous Infection of a Bovine Foetus by Two Fungi

RECENT investigations have shown that fungi are associated with bovine abortion in Hong Kong as in other countries. In each instance the probable pathogen was isolated and, except for one foetus, a single organism was considered to be the abortifacient. The exception, described here, occurred in a 6-month-old foetus which was infected by two fungi.

The material consisted of the foetal stomach and its contents, umbilical cord, heart and pieces of skin, and was examined and cultured within a few hours of abortion. It was examined macroscopically for visible symptoms of infection and also microscopically by squashing small pieces of tissue and by sections. To isolate the fungi small tissue slices were surface-sterilized by immersion in 95 per cent alcohol and then plated on to Sabouraud dextrose agar ('Oxoid'). Foetal stomach contents were extracted into a tube by pipetting through a sterile incision in the stomach wall; the fluid was then streaked on to the medium using a glass rod. All plates were incubated at 25° C and at ambient temperatures (approx. 30° C) and examined after 3 days when colonies which had developed directly from the tissues were subcultured for further examination. No bacterial tests were made as the parent had received routine protection against *Brucella abortus* and neither this bacterium nor *Vibrio fetus* had been isolated from foetuses in many other cases of abortion in the same herd.

Macroscopic examination of the skin and stomach contents indicated severe fungal infection of the foetus. Numerous discrete lesions were readily observed on the skin pieces. These were of variable size up to 5 mm diameter, pale in colour, and not restricted to any particular region. The stomach fluid contained visible aggregations of material and its consistency was considerably thicker than that from uninfected foetuses of the same age. This greater density was similar to that noted on examination of the stomach contents from other specimens of bovine mycotic abortion. No obvious lesions were seen on the other tissues examined.

Microscopic examination of squash preparations and sections showed numerous septate hyphae in the outer layers of skin tissue. No hyphae were seen in sections of the other tissues. Copious mycelium was found in the stomach fluid (Fig. 1). This had the broad, aseptate and branched structure typical of a phycomycete, and together with desquamated epithelial cells from the stomach wall constituted the visible aggregations.

No colonies developed from cultures of umbilical cord and heart tissue. However, cultures of stomach tissue and contents all yielded numerous colonies of *Mucor* after 3 days. These were sub-cultured and later iden-

Fig. 1. Hyphae of *Mucor dispersus* and desquamated epithelial cells in the stomach contents of an aborted bovine foetus

tified as *M. dispersus*, a species of this genus which does not appear to have been recorded previously as an abortifacient. No development of *Mucor* was recorded from any plate containing skin tissue. Fungus colonies also developed from each piece of cultured skin tissue but their rate of development was much slower. Sub-cultures from these yielded sterile grey-brown colonies of dematiaceous mycelium only. Although this organism grew readily on simple synthetic media all attempts to induce sporulation were unsuccessful.

Skin lesions are infrequent features of aborted foetuses in Hong Kong, although a survey elsewhere showed them to be present in almost half the cases examined<sup>1</sup>. In the foetus described it was not possible to ascribe the cause of abortion to either or both organisms. Numerous species of *Mucor* have been named as abortifacients and there have been many instances where fungi, although seen to be present by microscopic examination, have failed to develop and sporulate following abortion<sup>1</sup>. Simultaneous association of two fungi in bovine abortion is apparently of rare occurrence, and no reference to this phenomenon could be found in available literature. However, as the majority of fungal abortifacients are distributed both widely and abundantly, with concomitant opportunity to induce infection, it is possible that multiple infection occurs more frequently than the records suggest.

I thank Dr. G. D. Lowe for the material, and Mr. Ho Mang Hang for the photograph.

### Effect of Age and Hormonal State on the Numbers of Deoxyribonucleic Acid Synthesizing Nuclei in Rat Adrenal Cortex

THE use of tritiated thymidine to label nuclei synthesizing DNA (S-phase) prior to mitosis has provided much new information on the pattern and magnitude of cell turnover in many tissues and organs. Less is known, however, about the relative frequency of cell turn-over in the adrenal gland. Accordingly the investigation described here was undertaken to determine whether the number of nuclei in DNA synthesis in the different zones of the rat adrenal cortex varied with age and with experimental procedures designed to alter its hormonal environment.

To investigate the effect of age, 3 groups of normal rats near 60, 175 and 250 g body-weight were examined. All were albino males of an inbred strain, maintained on a commercial pellet diet and tap water. Tritiated thymidine (1  $\mu$ Ci/g) was given as a single intraperitoneal injection at 10 a.m. and the rats were killed 4 h later by bleeding under ether anaesthesia. Constant labelling times were maintained throughout this and subsequent experiments to avoid diurnal fluctuations in mitotic rhythm and DNA synthesis<sup>1</sup>. Autoradiographs of the adrenals were prepared

with Kodak 'AR 10' film, as previously described<sup>2</sup>, and the percentage of labelled nuclei (labelling index) in zona glomerulosa, the outer and inner parts of fasciculata, and zona reticularis was measured. In assessing fasciculata labelling outer and inner layers 8 cells in width were selected. The labelling index was calculated from counts of at least 1,000 nuclei in each zone per adrenal and, as far as possible, fibroblasts and vascular endothelial cells of the reticular framework of the gland were excluded.

The results for normal rats are shown in Table 1. The labelling index was highest in the outer layer of zona fasciculata at all ages. Labels were slightly less frequent in zona glomerulosa, and the inner fasciculata and reticularis zones contained few radioactive nuclei. In all zones, apart from zona reticularis, the labelling indices were significantly higher in young 60-g rats, reflecting the new cell formation necessary for active growth at this age and paralleled by frequent labelling of nuclei in other organs such as kidney and liver. The differences in labelling of adrenals from 175- and 250-g rats were marginal and not statistically significant, and this was taken as evidence of the relative stability of adrenal cortical nuclei in more mature animals maintained in normal non-stressful laboratory conditions.

The effect of variations in the hormonal state on the tritium-labelling index of the various adrenal cortical zones was examined in 4 groups. The first comprised 4 rats given adrenocorticotrophic hormone (ACTH) (10 units) daily for 14 days. The second group contained 8 rats given hydrocortisone (5 mg) daily for 28 days. The third consisted of 20 rats sensitized by unilateral nephrectomy and drinking 1 per cent sodium chloride as described by Selye, Hall and Rowley<sup>3</sup>, and given microcrystalline deoxycorticosterone (50 mg/kg) at 10-day intervals for 6 weeks. The final group of 8 rats with one kidney removed and drinking saline for 6 weeks served as controls. All hormones were injected subcutaneously. Tritiated thymidine was given and autoradiographs were prepared as already described here.

The results are summarized in Table 1. ACTH caused marked adrenal enlargement and a significant increase in the labelling index ( $P < 0.001$ ) in outer zona fasciculata when compared with normal rats of similar body-weight (173 g). Labelling of the other cortical layers was only slightly increased by ACTH and did not reach the limits required for statistical significance. Hydrocortisone induced adrenal cortical atrophy which obscured the junction between the glomerulosa and fasciculata zones and made certain identification of individual cell types less reliable. Accordingly counts of labelled nuclei in zona glomerulosa and the outer fasciculata layer were combined in the hydrocortisone-treated group ( $0.2 \pm 0.05$ ) and compared with a similar composite zone in normal 173-g rats ( $1.1 \pm 0.16$ ). Hydrocortisone significantly depressed the labelling index in this outer cortical layer ( $P < 0.001$ ), but had no effect on the inner fasciculata and reticularis zones. Sodium chloride, either alone or combined with deoxycorticosterone, significantly depressed the labelling index in zona glomerulosa ( $P < 0.001$ ) when compared with mature normal rats (247 g). The administration of deoxycorticosterone in these circumstances

\* Assessed from combined glomerulosa and outer fasciculata.

causes hypertension in a proportion of animals<sup>2</sup>, but the drinking of 1 per cent saline alone has little effect on the blood pressure. Since the reduction in glomerulosal labelling was equivalent in both groups it would appear that sodium chloride excess rather than hypertension was the important factor influencing cell turnover in zona glomerulosa in these experiments. Deoxycorticosterone and/or saline did not alter the labelling index in zona fasciculata but both reduced uptake in reticularis.

The use of tritiated thymidine as a flash-label<sup>4</sup>, as in the investigations recorded here, permits reliable measurements of the effects of age and hormones on cell turnover in the rat adrenal cortex. More extended investigations to trace the migration pathways and fate of labelled cortical cells might resolve at least some of the controversy concerning the zonal, centripetal, and transformation theories of adrenal cortical cell origin<sup>5</sup>. It is clear at present, however, that zona reticularis cannot be regarded as a completely senescent zone in the rat, for flash-labelled nuclei were present in all experiments. It is also apparent that prolonged treatment with either deoxycorticosterone or hydrocortisone, both of which have a well-recognized effect on adrenal morphology and biosynthetic capacity, does not thereby completely inhibit DNA synthesis in all nuclei in the appropriate cortical layer. Possibly the results we have obtained after such treatment approach the basal values of cell replacement that are necessary if the structural integrity of the adrenal cortex is to be maintained, even in an altered form.

### A Cytolytic Parasite in the Cells of Transplantable, Malignant Tumours

At this institute two transplantable ascites tumours, the Yoshida rat sarcoma and the Ehrlich mouse carcinoma, have for a number of years been kept alive by intraperitoneal passages and used in immunological research. Through these years each tumour after injection in rats and mice of the same strain has performed very consistently with a very low survival rate—about 5 per cent—and with uniform survival times before death from malignant ascites.

Testing another specimen of the Yoshida sarcoma we found two years ago a much higher survival rate—about 50 per cent—and much longer survival times after transplantation to our rats. Microscopic examinations of the ascitic fluid revealed some peculiar changes of the sarcoma cells. Further observations have shown these to be due to an intracellular infection by a parasite, which when found outside the cell shows a long flagellum.

The parasite is found, usually in great numbers, in the cytoplasm of the cells, most often as clusters filling vacuoles, or 'cysts' (Fig. 1), either in one large or in several small cysts. The number of parasites in each cyst ranges from three to about forty. Rarely, a few parasites are found scattered singly in the cytoplasm, and sometimes one or two parasites can be seen in the nucleus. In smears stained by Giemsa's method the parasite is small, measuring c. 1–2 $\mu$ . The size is rather uniform, the shape rounded or oval, although a few larger, elongated forms can be found, and each parasite displays some structural

Fig. 1

Fig. 2

differentiation. An unstained area occupies a large part of the cell, and a distinct, nucleus-like structure, taking a reddish-purple stain, is found in the periphery of this region, while the rest of the cell is evenly blue.

During the two years we have transferred the infected sarcoma a gradual adaptation between the parasite and the sarcoma cells has taken place, and the result of a peritoneal transfer now differs only slightly from what happens after injection of the uninfected Yoshida sarcoma. By now the survival rate closely approaches the low percentage of the uninfected sarcoma and the survival times are but slightly longer. When first observed the animals often produced large amounts of ascitic fluid with rather few sarcoma cells but now the fluid production is less severe, the cell counts having approached those of the uninfected sarcoma. The percentage of infected cells is rather constant, being about 25 per cent. Whereas subcutaneous injection of the uninfected sarcoma shows the same high percentage of 'takes' as intraperitoneal injection, the infected sarcoma does not produce any solid tumour when injected subcutaneously.

Rats surviving intraperitoneal transplantation are resistant to subsequent transplantation of the uninfected tumour. When killed at various intervals after injection of the infected tumour, however, a severe fibrinous peritonitis can be found leading to complete obliteration of the peritoneal cavity by fibrous adhesions. Attempts to cultivate the parasite in various bacteriological media have been unsuccessful.

While intraperitoneal injection of the uninfected rat tumour in mice produces no apparent ill-effects the infected rat tumour will by this route kill the majority of mice within six to ten days. In the mouse peritoneum the parasite multiplies rapidly and may readily be

observed by the phase-contrast microscope. Fig. 2 shows the appearance of an extracellular parasite, the flagellum being noticeable. Rats made resistant to transplantation by the intracoeal vaccination of Lund<sup>1</sup> are clinically unaffected by intraperitoneal injection of the parasitized tumour, so the rats do not show a susceptibility to the parasite itself as found in mice. At present it seems probable that the parasite can be cultivated by intraperitoneal passage in mice, although in small numbers.

By intraperitoneal transplantation of the Ehrlich carcinoma and subsequent introduction of the parasite I have recently been able to develop an infected, transplantable Ehrlich carcinoma in mice, the tumour cells, however, disappearing after nine passages.

The establishment of a transplantable, parasitized, malignant tumour in each of two species of animals and the cytolytic property of the parasite towards the cancer cells make identification desirable. A parasite has recently been described by Nelson<sup>2</sup> and by Werner and Pierzynski<sup>3</sup>, associated with ascites in white mice, which shows important similarities in morphology and behaviour to a possible point of identity with the parasite described in this communication. In none of these cases, including that now described, has the source of the parasite been found, but even the parasite described by Nelson was connected with experimental cancer research, as it was found in mice examined because of an atypical response to certain chemical carcinogens. Nelson suggests classification in the protozoan order Microsporidia. The mutual adaptation between tumour and parasite may be overlooked and might be misleading, in the experimental use of transplanted tumours.

## Role of the Fibrous Capsule in Carcinogenesis by Plastic Film

THE ability of materials in the form of a film to induce sarcomas at the site of implantation was first shown by Turner in 1941<sup>1</sup> when he implanted disks of 'Bakelite' subcutaneously in rats. Oppenheimer and his associates re-discovered this phenomenon in 1948<sup>2</sup>. Later, they extended their work to show that the same applied to mice and that many different kinds of plastic film, metal foils, and glass cover slips were capable of inducing sarcomas<sup>3,4</sup>. Few tumours developed when the same materials were implanted in the form of powders, granules, or sponges<sup>5</sup>.

The importance of the physical form of the materials for tumour-induction has been generally recognized, but the mechanism by which the film acts is still poorly understood. Oppenheimer *et al.* carried out histological studies comparing the reaction around a piece of film with the reaction around a textile of the same material<sup>6</sup>. The film became surrounded by a fibrous capsule which by six months had become avascular and relatively acellular. Connective tissue fibres penetrated the textiles, but no capsules formed around them. At varying periods after six months, renewed fibroblastic activity, which they felt was a pre-sarcomatous stage, was seen in the inner aspects of some capsules. They found that the plastic film could be removed from the capsules after six months without affecting the number of tumours which developed. Removal before this time prevented sarcoma formation.

Since the discovery by Malmgren *et al.*<sup>7</sup> that a number of carcinogenic chemicals suppressed antibody formation in mice, and the discovery by Foley<sup>8</sup> and by Prehn and Main<sup>9</sup> that methylcholanthrene-induced sarcomas in

mice contain new antigens which are not present in the normal tissues of the host, there has been speculation that carcinogenic activity may be directly related to the ability of a substance to suppress the immune mechanism. The fact that the plastic film no longer had to be present after six months in Oppenheimer's experiment, and that by this time the fibrous capsule around the film had become dense and avascular, suggested that in this type of carcinogenesis as well, suppression of the immune mechanism might be an important factor. The dense fibrous capsule might act as a barrier to immunologically competent cells, thus functioning in the same manner as a 'Millipore' diffusion chamber<sup>9</sup>; or the avascularity of the inner layers of the capsule might result in delayed vascularization of the developing tumour<sup>10</sup>. In this protected environment, it is possible that antigenically altered 'mutant' cells could survive and proliferate, whereas they might be destroyed in a site more accessible to the host's immune mechanism. This work was designed to determine whether the interior of the capsule is a preferred site for survival of antigenic tumours.

Three separate experiments were performed. In each, the skin on the dorsum of *BALB/cAn* mice six to twelve weeks old was incised, and a round piece of plastic film was placed in the subcutaneous tissue beneath the panniculus carnosus. Approximately nine months after implantation of the film, the skin was incised and lifted away from the body until the film and its surrounding fibrous capsule were found. In the experimental animals, a small slit was made at one edge of the capsule, and a piece of a transplanted fibrosarcoma which had been induced by 3-methylcholanthrene in a *DBA/2* mouse was injected into the space beside the film through a 21-gauge trocar. The trocar was inserted through the slit in the capsule, and the tumour was placed at the side of the capsule opposite the slit. In the control animals, the tumour was injected into the subcutaneous tissue adjacent to, but not inside, the fibrous capsule.

The three experiments varied somewhat with respect to the sex of the mice, the transplant generation of the tumour, and the size and material of the plastic. In Experiment 1, there were six females and ten males which were allocated equally between experimental and control groups. A first transplant generation tumour was used for inoculation. The film consisted of 'Cellophane' dialysing membrane 8 mm in diameter. In Experiment 2, 18 males received film consisting of 'Millipore' filters which had been fused with acetone. These were 20–23 mm in diameter. A second-generation tumour was transplanted. In Experiment 3, 'Cellophane' dialysing membrane 14 mm in diameter was used. The tumour was in the second generation when it was transplanted.

The animals were checked at weekly intervals for growth of the transplanted tumours. In several cases, there appeared to be growth during the first three or four weeks after transplantation, followed by regression. Table 1 summarizes the results. In the column headed 'Tumours grew progressively' are included tumours which showed progressive growth for more than two months and reached a size of at least 12 mm in diameter before the animals were killed. The column headed 'Tumours grew > 5 mm in diameter' includes both the tumours which grew progressively and those which grew to at least 5 mm in diameter as measured by palpation through the skin, but which then regressed. Nodules

Table 1. SURVIVAL OF HOMOLOGOUS TUMOURS INSIDE AND OUTSIDE FIBROUS CAPSULES

Total	32	32	14	5	25	8

$\chi^2 = 4.7906$   
 $P < 0.05$

$\chi^2 = 16.0156$   
 $P < 0.001$

less than this size were not included because of the difficulty in determining whether growth had really occurred. Since the plastic film itself induces sarcomas, it was necessary to determine whether the progressively growing tumours were of *BALB/c* or *DBA/2* origin. In Group I, it was assumed that all were of *DBA/2* origin since in a control group of fifty *BALB/c* mice implanted with the same type and size of film at the same time, the first tumour did not arise until 17 months after implantation. In Groups II and III, however, a few tumours had developed at the site of implantation before the *DBA* tumours were inoculated. With these groups, the strain of origin of each progressively growing tumour was determined by evaluating its growth on transplantation to *DBA/2* and (*BALB/cAn* × *C<sub>3</sub>H/He*)*F<sub>1</sub>* hybrids.

These results demonstrate that the fibrous capsule which forms around a piece of plastic film inserted subcutaneously is a preferred site for survival and growth of moderately antigenic tumours. This is indicated best by the figures related to progressive growth of the transplanted tumours. The figures which include 'tumours' which grew for a period and then regressed must be viewed with caution because those tumours were not studied histologically. It is possible that some were bacterial abscesses resulting from contamination at the time of inoculation. The reason for the preferential survival within the capsules is not demonstrated. The tumour which was transplanted was antigenically different from the host, though it did not differ with respect to the strong *H-2* antigens. Even so, the tumour was probably more strongly antigenic with respect to its homologous host than plastic film-induced tumours appear to be in isologous hosts<sup>11</sup>. The results are thus compatible with the hypothesis that the capsule acts as a barrier to the immune mechanism, but they do not prove it. Tumours may grow better within the capsule for other reasons. If it can be shown that isologous tumours which are not antigenic for their strain of origin do not grow better within the capsule than outside, the hypothesis that the capsule acts as a barrier to the immune mechanism will be more firmly established.

## HISTOLOGY

### Histochemical Demonstration of Conjugated and Unconjugated Bilirubin using a Modified Diazo-reagent

• Most of the methods proposed for the staining of bilirubin in tissues involve oxidation of the pigment with production of coloured compounds such as biliverdin<sup>1-5</sup>. Only conjugated bilirubin appears to be stained

by such techniques, and negative results have been reported with brain tissue from infants with kernicterus. The diazo reaction also has been used to stain bilirubin in tissues<sup>6,7</sup>, but attempts to show different types of bilirubin have not met with success<sup>8</sup>.

This communication describes a method for a van den Berg reaction at a histochemical level. Unfixed cryostat sections stained with diazotized dichloraniline demonstrate the presence, in tissues, of conjugated bilirubin, which gives a 'direct reaction' in aqueous solution, and unconjugated bilirubin, which only reacts in the presence of a suitable accelerating solution. The use of dichloraniline was proposed by Rand and Di Pasqua<sup>9</sup> for serum bilirubin estimations.

The stock solutions were: *A*, dissolve 200 mg 2,4-dichloraniline in 100 ml. water containing 2.5 ml. conc. HCl and filter; *B*, 1 per cent sodium nitrite (both solutions *A* and *B* should be freshly prepared every two weeks and kept in the dark in a refrigerator); *C*, dissolve 6 g caffeine, 10 g sodium benzoate and 10 g urea in 100 ml. water. To 35 ml. of this solution add 25 ml. 40 per cent formalin and make the volume up to 85 ml. with water, then add 15 ml. methyl ethyl ketone.

The reagents should be freshly prepared and kept in an ice bath: (1) aqueous diazo reagent—add 1 vol. solution *B* to 50 vol. solution *A* and leave for 20 min in an ice bath before use; (2) accelerator-diazo reagent—add 1 vol. of aqueous diazo reagent to 2 vol. of solution *C*.

Tissue is rapidly frozen and 6μ cryostat sections are cut, mounted directly on to slides and allowed to dry for 1 h, in the dark, at room temperature. If necessary, sections can be kept in a cool dark place for several weeks without loss of staining properties.

(1) To demonstrate conjugated bilirubin ('direct' reaction): (i) immerse slides for 10 min in aqueous diazo reagent; (ii) wash for 3 min in running tap water; (iii) fix for 3 min in 10 per cent formol saline; (iv) counter-stain with haematoxylin, if desired, and mount in Apathy's syrup. Conjugated bilirubin is stained blue-violet.

(2) To demonstrate both conjugated and unconjugated bilirubin: untreated sections or sections previously stained by the aqueous diazo reagent, but not fixed, can be used. (i) immerse sections for 8 min in the accelerator-diazo reagent; (ii) wash in running tap water for 3 min; (iii) counter-stain with haematoxylin if desired, and mount in Apathy's syrup. Bile pigments in the section are stained red. Other pigments, such as lipofuscin, remain unstained.

With this method it has been possible to demonstrate in human liver and kidney from patients with cirrhosis and obstructive jaundice the presence of a yellow pigment, mainly localized in bile canaliculi (Fig. 1), which gives a 'direct' reaction with an aqueous solution of dichloraniline. This reaction is not given by the pigment present in livers of Gunn rats, whose only bile pigment is unconjugated bilirubin. It therefore seems likely that the pigment which has been stained is conjugated bilirubin, the major part of which is bilirubin glucuronide<sup>10</sup>.

Although extension of the staining time does not increase the amount of pigment stained, it is possible that, for technical reasons, some of the conjugated bilirubin in the tissue remains unstained by the aqueous diazo reagent. There seems, however, little doubt that, qualitatively, a positive reaction is indicative of the presence of bilirubin glucuronide in the liver cells and bile canaliculi.

The accelerator-diazo reagent gives extensive staining of liver cells, Kupffer cells and bile canalicular contents. When added to tissue which has previously been stained with the aqueous diazo reagent, further staining immediately occurs (Fig. 2), sufficiently intense to be seen with the naked eye. This reaction will be given both by any conjugated bilirubin which has not been previously stained, and by the unconjugated bilirubin. It stains the pigment of Gunn rat liver.

Fig. 1

Fig. 2

Figs. 1 and 2. Needle biopsy of liver from a patient with large bile duct obstruction

Fig. 1. Stained with aqueous diazo reagent showing the conjugated bilirubin in blue violet (shaded black in picture) ( $\times c. 385$ )

Fig. 2. The same field stained with accelerator diazo reagent, showing conjugated and unconjugated bilirubin in red (shaded black in picture). Note staining much more intense than in Fig. 1, especially within the cells ( $\times c. 385$ )

With this procedure it is possible to examine sections stained for the bile pigments within a few minutes of receiving a specimen. The application of the technique to liver biopsy material is at present under investigation.

## BIOLOGY

### Increase in Fruit Set of *Vitis vinifera* by Treatment with Growth Retardants

FRUIT set of seedless cultivars of the grape (*Vitis vinifera* L.) has been improved by treatment with auxins<sup>1,2</sup>, gibberellins<sup>3</sup>, and kinins<sup>4</sup>. By contrast, fruit set of seeded cultivars has not been improved by treatment with these growth regulators. For two reasons, the set of seeded and seedless grapes has been examined further: first, to examine the effect of pre-anthesis treatments—previous

experiments have for the most part been confined to application at or soon after anthesis, whereas earlier treatments have been shown to increase fruit set in pears<sup>5</sup> and apples<sup>6</sup>; secondly, to compare regulators which have been classified as auxins and gibberellins with anti-auxins and anti-gibberellins (or growth retardants); the latter group has not previously been tested on grapes.

Single inflorescences were treated on vines growing in the field by a momentary dip in the appropriate aqueous solution containing 0.05 per cent v/v 'Tween 20'. All treatments were applied to one vine as a replicate, and there were nine replicates. Three times of treatment were compared: 2–3 weeks pre-anthesis, anthesis, and 2–3 weeks post-anthesis. When mature, the inflorescences were gathered and measurements made of the number of berries set, and other variables.

The two substances classed as growth retardants, 2-chloroethyltrimethylammonium chloride (CCC or 'Cycocel') and tributyl-2,4-dichlorobenzylphosphonium chloride ('Phosfon-D'), when applied before anthesis, considerably increased the number of berries set on three cultivars (Table 1). There were differences between these three cultivars in the response obtained, and the fourth cultivar, 'Doradillo', did not respond to either. In no case was set increased significantly by treatment with these substances at, or after, anthesis.

Besides the growth retardants, gibberellic acid (GA<sub>3</sub>) also altered the set and development of grape berries when applied before anthesis. The effects of CCC and GA<sub>3</sub> on the seeded cultivar, 'Muscat of Alexandria', are compared in Table 2 and Fig. 1. CCC increased fruit set by increasing the number of seeded berries per cluster, with a commensurate increase in cluster weight. Its only other effect was to increase slightly the size of seedless berries. The rachis, pedicel, seed and flesh tissue appeared

Table 1. Effect of dipping grape inflorescences in solutions of CCC and 'Phosfon-D' (100 mg/l.) 2 to 3 weeks before anthesis, on the total number of berries set per inflorescence, measured when ripe

Cultivar	Expt. No.	Untreated	CCC	'Phosfon-D'
'Zante currant'	1	244	403*	279
	2	276	581*	588*
'Sultana'	3	231	299	408*
'Muscat of Alexandria'	4	88	138†	128*
'Doradillo' (syn. 'Jaen')	5	227	226	172

\*, † Values significantly greater than untreated at probabilities > 1 per cent and 0.1 per cent respectively.

Table 2. Effects of dipping 'Muscat' inflorescences in solutions of CCC (100 mg/l.) and GA<sub>3</sub> (20 mg/l.) 18 days before anthesis, on the fruit measured 130 days later (Experiment 4)

	Untreated	CCC	GA <sub>3</sub>
Cluster fresh weight (g)	241.0	406.0†	223.0
Cluster length (cm)	19.8	19.9	25.4†
No. of berries per cluster	seeded	68.0	120.0†
	seedless	20.0	18.0
	total	88.0	138.0†
Percentage of seedless berries	23.0	13.0‡	83.0†
Seeded berries	fresh wt. (g)	3.86	3.67
	length (mm)	19.6	18.9
	width (mm)	18.0	17.9
Seedless berries	fresh wt. (g)	0.93	1.24*
	length (mm)	11.2	12.7*
	width (mm)	10.4	12.2†
Juice sugar content by refractometer (%)	22.5	23.0	25.2†

\*, †, ‡: values significantly greater than untreated at probabilities > 5 per cent, 1 per cent and 0.1 per cent, respectively. (‡, †: significantly less than untreated).

to be unaltered. GA<sub>3</sub> also increased fruit set, but most of the berries were seedless; cluster weight remained the same as untreated because of the lighter weight of seedless berries. The berries were longer and narrower than untreated, and also sweeter. All parts of the inflorescence framework were elongated and the rachis became 'wiry' (Fig. 1).

Subsequent trials have confirmed the effect of CCC in increasing grape set, particularly in 'Muscat'. To be effective, it may be applied as a cluster dip or a vine spray, but it must be applied before anthesis. Frequently the treatment results in smaller berries, although cluster weight is still increased because of the large increase in set.

An interesting aspect of these results is that the three cultivars which responded to growth retardants have different types of berry development: 'Zante Currant' is parthenocarpic, 'Sultana' is stenospermocarpic (that is, the seeds abort when half grown), and 'Muscat of Alexandria' is seeded. So far as I am aware, these are the first chemical treatments which have caused a large increase in the set of grapes with seeds.

This effect of growth retardants seems unusual when compared with their other effects. For example, they retard stem growth and internode elongation, fatten stems, slow leaf blade expansion, make leaves darker green and delay seed germination<sup>7</sup>. Many of these effects are opposite to the effects of gibberellic acid and have led to their designation as anti-gibberellins. In fact, it has been shown that simultaneous treatment with gibberellic acid prevents these substances from retarding stem

Fig. 1. Typical 'Muscat' clusters from the experiment described in Table 2: left, CCC; middle, untreated; right, GA<sub>3</sub>.

elongation<sup>8</sup>. From the results in Table 2 the only variables where GA<sub>3</sub> and CCC show opposite effects are the number of seeded berries per cluster and the percentage of seedless berries. It remains to be seen whether these effects are related or whether the substances interact when applied together. Nothing is known about the mechanism of this effect on set, but, in view of the effects of these compounds on other plant growth processes<sup>9,10</sup>, it is likely that an investigation of the mechanism will aid our understanding of the fruit setting process.

### Lateral Movement of Inorganic Solutes in Plants

PREVIOUS work in inorganic solute movement in plants has suggested that the minerals follow a specific polar path from the roots which absorb them to the leaves in which they are deposited<sup>1,2</sup>. Recently, evidence supporting polar transport has been provided by Caldwell using a split root technique<sup>3</sup>. It was established that when the root systems were placed half in rich loam and half in sand the nutrient status of the two halves was reflected in the development of the foliage directly above. This result was interpreted as a polar movement of nutrients. However, the important issue is not whether polar movement can occur, but whether it must occur, owing to the absence of lateral transport systems.

*Coleus* is particularly suitable for an investigation of this kind because the main vascular bundles are situated at the angles of the square stem. We used Caldwell's split root technique on *Coleus frederici*. Cuttings were taken and a fortnight later the rooted stumps were carefully split from the base upwards, and the plants potted so that each half of the root system was contained in a separate pot (Fig. 1). In this way the nutrition and water supply of the two halves could be varied independently.

Fig. 1. The split root system technique and possible lateral transport system

Fig. 2. The plant which has wilted (left) recovers completely in a few hours (right) after watering side *A* only

Fig. 3. Typical foliage from plants with differing nutrient and water status, sides *A* and *B*. +, Complete nutrient solution; -, nutrient solution deficient in phosphate

First, experiments were conducted with plants rooted (*A* and *B*) in loam. When side *A* was liberally watered and side *B* allowed to dry out no visible signs of stress could be induced in the foliage above *B*, indicating the ready lateral movement of water. This deduction was confirmed in separate experiments by allowing *A* and *B* to dry until all the foliage wilted. On watering one side (*A*) only, rapid recovery occurred in the foliage of both sides (*A* and *B*) (Fig. 2).

It was then postulated that salts might be carried along with this lateral movement of water. This was investigated by rooting the cuttings in sand cultures, and giving both sides only de-ionized water before the addition of nutrients. When side *A* was then fed complete nutrient and side *B* on phosphate-deficient solution, the treatment resulted in visible deficiency symptoms of the foliage on side *B*, confirming Caldwell's experiment. In another series of experiments side *B* was given no nutrient solution, and was allowed to dry out while side *A* was fed on a complete nutrient solution. With this treatment the foliage of *A* and *B* was healthy and normal (Fig. 3).

Dry weights were obtained of all leaves and axillary branches on the orthostichies above the sand. Alternate

leaves (from the median orthostichies) were rejected. These results indicate that lateral movement of phosphate can occur in response to a change in the water potential gradient. Polar transport is not obligatory. Experiments involving partial defoliation with lateral incisions provided further confirmation for the conclusion that certain solutes are transported by the transpiration stream irrespective of its path.

In whole plants the water tensions exerted by foliar evaporation cause the transpiration stream to move through the vascular xylem which offers least resistance to flow. Lateral tensions are usually small in plants and hence solutes carried by the transpiration appear to follow a specific polar path. However, after appropriate treatment lateral tensions develop in the plant which induce lateral movement of both water and solutes, thus proving the existence of a lateral transport system.

We thank Prof. P. E. Weatherley for his advice.

### Effect of Cobalt on the Non-nodulated Legume

It has been demonstrated on several occasions that the addition of small quantities of cobalt as a nutrient has a stimulating effect on the growth of nodulated legumes<sup>1-3</sup>, whether they are grown in water culture, in sand culture or in the field. This has generally been attributed to an effect on the symbiotic fixation of nitrogen by the nodule, and the discovery that cobamide co-enzymes are present in the nodules of several leguminous species, as well as in the nodules of certain non-legumes<sup>4</sup>, enhances the probability of this hypothesis.

We have recently examined further the possibility that the legume itself, as distinct from its symbiont, has a requirement for cobalt, and this has been found to be the case. The relatively high degree of contamination by cobalt from the atmosphere has caused some difficulties. In several experiments using subterranean clover as the test plant, measurement of maximum radius<sup>5</sup> of the plants showed a clear-cut difference in the early stages which disappeared completely as the plants aged, and this effect was worse in the constantly disturbed air of a growth room than in the quieter air of a glasshouse. We have now been able to obtain a response on a sufficient number of separate occasions to leave no room for doubt. One set for plants grown in water culture in nutrient containing 5,000  $\mu\text{M/l}$ . nitrate nitrogen, and harvested at 50 days old, was as follows:

Co added  $\mu\text{M/l}$ . 0.0 0.02 0.20 2.00

Dry wt. 0.80 0.92 1.03 0.06

Difference for significance in dry wt. at 5 per cent 0.15, at 1 per cent 0.22.

An analogous stimulation has also been found in plants nodulated with an ineffective strain<sup>6</sup>. Since radioautographs using <sup>60</sup>Co suggested that cobalt was concentrated in the root tips, as well as in the nodules, some investigation has been made of the metabolism of the different parts of plants growing in nutrient solutions with and without added cobalt. Several differences have been observed, but perhaps the most notable is that, whereas no effect is shown by the leaves, the nodules and root tips of the +cobalt plants show a higher respiration rate than those of the -cobalt plants, when expressed on a dry matter basis. When calculated on the basis of total nitrogen content, however, the difference between the nodules of the two treatments became non-significant.

Table 1. DRY-WEIGHT OF LEAVES AFTER VARIOUS TREATMENTS

Dry-weight (g)	<i>A</i> Complete	<i>B</i> Deficient	<i>A</i> Complete	<i>B</i> Dry
Replicate (1)	2.492	0.668	1.364	1.610
(2)	1.294	0.656	1.106	1.618
(3)	1.610	0.710	1.456	1.563
Means	1.799	0.678	1.309	1.597

Fig. 1. Respiration of nodules and root tips (50-day plants)

The respirometer curves for the nodules and root tips are given in Fig. 1.

Apart from the general interest in the possible role of cobalt in the metabolism of a plant, this appears to be the first time that a differential requirement for a nutrient has been found, when the leaf tissues of a plant show no response to an element which has a marked and characteristic effect on the metabolism of the roots.

## MICROBIOLOGY

### Preparation of <sup>14</sup>C-D(—)-β-hydroxybutyric Acid from <sup>14</sup>CO<sub>2</sub> using 'Knallgas' Bacteria (*Hydrogenomonas*)

ORGANISMS which fix carbon dioxide can be used to advantage for the preparation of radioactive labelled compounds. During growth, radioactive carbon from <sup>14</sup>CO<sub>2</sub> can be incorporated into all cellular substances. If growth is inhibited, assimilated carbon is bound primarily in the form of reserve material. Several 'knallgas' bacteria of the *Hydrogenomonas* type incorporate <sup>14</sup>CO<sub>2</sub> into poly-β-hydroxybutyric acid (PHBA) in a hydrogen-oxygen atmosphere in the absence of a source of nitrogen<sup>1,2</sup>. PHBA can be depolymerized to D(—)-β-hydroxybutyric acid (HBA) by using either hydrazine<sup>3</sup> or enzymatic hydrolysis<sup>4,5</sup>.

<sup>14</sup>C-PHBA is prepared using the apparatus shown in Fig. 1. Chemolithotrophically grown cells<sup>6</sup> are gathered, washed, and suspended (0.5 mg dry weight/ml.) in a nitrogen-free mineral medium. From this suspension 100

Fig. 1. Apparatus for the preparation of <sup>14</sup>C-poly-β-hydroxybutyric acid. P, connexion to vacuum pump; S, bacterial suspension; M, magnetic stirrer; T, constant temperature bath; D, flask containing barium carbonate-<sup>14</sup>C; E, 10 per cent perchloric acid; G, washing tower containing 20 per cent KOH; H, hydrogen-oxygen mixture

ml. are pipetted into the 2 l. round flask and stirred at a temperature of 30° C. After opening stopcocks A, B, and C, 5 l. of carbon-dioxide-free 'knallgas' (70 per cent H<sub>2</sub> + 30 per cent O<sub>2</sub>) are allowed to flow through the apparatus. After closing stopcock A, the suspension is stirred for a further 30 min, stopcock B is then closed and the main reaction flask evacuated through stopcock A. Perchloric acid, 15 ml. of a 10 per cent solution, is then allowed to flow into flask D, which contains barium carbonate-<sup>14</sup>C (5 mc.). By opening stopcock B and C the <sup>14</sup>CO<sub>2</sub> which has been generated is carried over into the main reaction flask by the incoming 'knallgas' until the pressure is equilibrated. Stopcock B is now closed and the suspension stirred for 3 h. At the end of this time, the cells are killed with formic acid, washed and lyophilized. PHBA is isolated by using a sodium hypochlorite solution<sup>7</sup> or by means of chloroform extraction and is then hydrolysed. From 5 mc. of barium carbonate-<sup>14</sup>C (spec. act. 20–26 mc./m.mole), a yield of 3–3.5 mc. of HBA (60–70 per cent theoretical) with a specific activity of 12–20 mc./m.mole was obtained in a number of experiments.

### Growth of 'Knallgas' Bacteria (*Hydrogenomonas*) using Direct Electrolysis of the Culture Medium

IN view of the recent discussion pertaining to the use of the 'knallgas' bacteria for the regeneration of exhaled air<sup>1–3</sup>, we should like to point out that it is possible to produce the oxygen-hydrogen mixture directly in the culture vessel by electrolysis of the mineral medium. Since the 'knallgas' bacteria of the *Pseudomonas* type (*Hydrogenomonas* strains H 16 and H 20) grow in chloride-

Fig. 1. Growth of *Hydrogenomonas* strain H 16 using electrolysis of culture medium for production of hydrogen and oxygen. Mineral medium (1 l.) was contained in a 2-l. culture vessel whose contents were magnetically stirred. Hydrogen and oxygen were produced using 2 platinum electrodes, each 16 cm<sup>2</sup>, at currents of 200, 400 and 600 m.amp. Turbidity of the cell suspension properly diluted (ext. < 0.3) was measured at 420 nm with 1-cm cuvettes (Zeiss Elko III)

free medium, oxygen and hydrogen can be produced in such a medium without interfering with side-effects using platinum electrodes with a relatively large surface area. Carbon dioxide is led directly into the culture vessel and removes excess oxygen. By using currents between 0.1 and 1.2 amp and at voltages not exceeding 5.3–5.5 V, good growth is achieved<sup>1,4</sup>. At low current-levels, growth is proportional to, and limited by, the hydrogen produced.

During growth, hydrogen, oxygen and carbon dioxide are consumed in the ratio of 8 : 3 : 1. Bacteria grown under these conditions can withstand a very high partial pressure of oxygen and contain very little reserve material (poly- $\beta$ -hydroxybutyric acid). Since hydrogen and oxygen are directly produced and consumed in the culture vessel, the electrolysis-culture method is simpler and less dangerous than other methods for the autotrophic growth of 'knallgas' bacteria. This method offers a number of distinct advantages for automatic continuous cultures.

## ENTOMOLOGY

### Temperature Regulation in the Sphinx Moth during Flight

THE ability of some insects to raise the thoracic temperature by muscular activity above that of the surrounding air is well known<sup>1</sup>. However, we have demonstrated recently that the internal heat produced is regulated during periods of activity<sup>2</sup>. The investigation reported here shows that the moth, *Celerio lineata*, maintains a relatively constant body temperature during flight over a range of ambient temperatures.

We previously described a method of implanting thermistors and recording the body temperature of moths without hindering normal behaviour<sup>2</sup>. The same techniques were used here, but, to obtain extended periods of continuous flight, the moths were hung on the probe leads and stimulated to make flight movements. Tem-

peratures were recorded of moths subjected to ambient temperatures ranging from 10° C to 35° C.

The moths maintained thoracic temperatures between 32° C and 40° C. Rapid changes in ambient temperature during tethered continuous flight failed to produce correspondingly large changes in thoracic temperature. The thoracic temperatures in Fig. 1 represent levels maintained for longer than 15 sec during flight. A few values are included for the maximum temperature after increases in thoracic temperature in cases where equilibrium was not established; these demonstrate achievable levels at low ambient temperatures. If heat production during flight were constant, independent of ambient temperature, as in the migratory locust<sup>3,4</sup>, the thoracic temperature would be parallel to the isothermal line. However, our data suggest that heat production increases at low and decreases at high ambient temperatures. The thermal levels maintained during flight are consistent with the levels reported by Adams and Heath<sup>2</sup> during voluntary mixed activity.

Fig. 1. Thoracic temperatures maintained by flying *Celerio lineata* plotted against ambient air temperatures. The arrows show the mean regulated range during voluntary mixed activity (ref. 2)

Flight at low ambient temperature is vigorous, but it becomes intermittent at higher temperatures where even the minimal output of flight energy places the animal under heat stress. At air temperatures above 30° C, the moth may regulate behaviourally by periodic landing and cooling. These results are exactly contrary to those of Church, showing that the migratory locust generates a constant body temperature excess of 6° C over an 11-degree range of ambient temperature during flight<sup>4</sup>. This difference may be related to the biology of the two animals. The nocturnal moth, lacking radiant heat sources, must rely on its own heat production to achieve and sustain the high body temperature required for activity, while the diurnal locust can regulate its body temperature by appropriate behavioural responses to radiant heat sources. Under high day-time temperature conditions the temperature excess resulting from flight in the locust may on occasion cause overheating. Activity may then be curtailed until more equable thermal conditions obtain. On the other hand, the usually cool night-time temperatures encountered by large moths allow the establishment of a favourable gradient to the environment, so that overheating might restrict activity only on nights when the air temperatures are above 30° C.

This evidence further substantiates the idea that at least some insects may be nearly homeothermic during

periods of activity. It further indicates that *Celerio lineata* is capable of distinguishing differences in thoracic temperature and of adjusting the heat output of the flight muscles during flight to compensate for changing external thermal stress.

## VIROLOGY

### Mutual Precipitation of Two Viruses

SOME, but not all, pairs of proteins which are oppositely charged combine with and precipitate each other when mixed in salt-free solutions<sup>1</sup>. The precipitates usually dissolve when salt is added, presumably because anions and cations of the salt substitute the negatively and the positively charged proteins, respectively, in the compound formed by electrostatic attraction.

Until recently it seemed improbable that pairs of viruses would precipitate each other by electrostatic attraction, for those examined mostly had iso-electric points near pH 4.5 with deviations from this value by less than two pH units. The possibility became evident with the knowledge that bromegrass mosaic virus (BMV) is iso-electric at about pH 8.0 (ref. 2) and satellite virus (SV) (ref. 3) at about pH 7.0 (Fig. 1). To investigate the possibility, tests were made to see whether these viruses would precipitate with tobacco mosaic virus (TMV), because there is a wide range of pH values at which they are positively charged and TMV is negatively charged (Fig. 1). At any pH value within this range BMV is considerably more charged than SV and thus appeared more likely to precipitate with TMV than SV.

Fig. 1. Electrophoretic mobilities of TMV, BMV and SV at different pH values. The curve for TMV was taken from Kramer and Wittmann<sup>4</sup> and that for BMV from Bockstahler and Kaesberg<sup>3</sup>. They were obtained in buffers of ionic strength of 0.075 and 0.1, respectively. The curve for SV was obtained in the present work in M/15 phosphate buffer using a Perkin-Elmer electrophoresis apparatus. As isoelectric points and relative charge densities can depend on the presence of salt, any comparisons between TMV, BMV and SV, based on the curves shown above, apply only approximately to salt-free solutions.

When equal volumes of salt-free solutions of BMV and TMV at 1 g/l., adjusted to pH 5.0 with hydrochloric acid or sodium hydroxide, were mixed, a precipitate formed immediately, and when it had settled neither virus was detectable spectrophotometrically in the supernatant fluid. Precipitation occurred at all pH values between 4.0 and 6.5 and was most rapid at about pH 5.0. Adding sodium chloride to a concentration of 0.4 per cent or more immediately dissolved the precipitate.

By contrast, mixing salt-free solutions of SV and TMV in similar conditions did not produce a precipitate, and no interaction between the two viruses was detected when the mixture was examined in an analytical ultracentrifuge.

TMV and SV probably failed to interact because the charge density of SV was too small; at pH 5.3 (which is near optimal for precipitation between TMV and BMV) the electrophoretic mobility of SV (measured at 1 g/l. in M/15 phosphate buffer) is only about +0.1 μsec/V/cm, whereas that of BMV is about +0.3 μsec/V/cm. The mobility of BMV is slowed to about +0.1 μsec/V/cm when the pH is raised to just over 6.5, and at this pH BMV also fails to precipitate with TMV in spite of the fact that the raising of the pH slightly increases the negative charge density of TMV.

Salt-free solutions of SV and of yeast nucleic acid (1 g/l.) also failed to precipitate when mixed at pH 5.0, whereas solutions of BMV and of the nucleic acid immediately produced a precipitate that dissolved when sodium chloride was added to a concentration of 2 per cent. pH 6.0 was the upper limit at which a precipitate formed.

In salt solutions in which TMV and BMV do not precipitate one another they also fail to combine, for when a mixture of the two viruses in M/15 phosphate buffer at pH 5.3 was subjected to electrophoresis, the mobility of each virus and the size of the peak formed by it were the same as when it was used alone.

A suspension of the precipitate formed by mixing equal amounts of TMV and BMV caused numbers of local lesions on leaves of *Nicotiana glutinosa* similar to those caused by an equal amount of TMV inoculated alone.

### Inhibition of Virus Growth by a Toxic Factor from Asbestos Pad and Cellulose Acetate Membrane Filters

HOUSE<sup>1</sup> has shown recently that a factor which is toxic for baby hamster kidney cells (BHK 21, ref. 2) is eluted from asbestos pads by Eagle's tissue culture medium. This toxic factor inhibits to a marked degree the cloning efficiency of the clone C 13 which he used.

This observation by House appeared to be related to observations we had made previously during the preparation of a phosphate-low medium which we required for the growth of phosphorus-32-labelled foot-and-mouth disease virus<sup>3</sup> in both pig kidney and baby hamster kidney cells. Using a formula based on Hanks's saline, but containing *tris* buffer instead of phosphate, we found in preliminary experiments that the yields of virus were the same as those in unmodified Hanks's saline. Unexpectedly, filtration of the phosphate-low medium through a Seitz E.K. asbestos pad resulted in a considerable reduction of virus yield. In view of House's observations we have now carried out further experiments to determine whether a toxic factor was responsible for the reduction in virus yields which we encountered in our preliminary experiments. Through Mr. House's co-operation we have been able to

Table 1. EFFECT OF FILTRATION OF MEDIUM ON GROWTH OF FOOT-AND-MOUTH DISEASE VIRUS IN PIG KIDNEY AND BABY HAMSTER KIDNEY CELLS

Medium	Filter	Cell and virus type	Virus yield (ml. 1/30 C' fixed by 1 ml.)	Infectivity titre (mouse $ID_{50}$ /0.03 ml.)
Phosphate-low	Unfiltered	Pig kidney C 997	0.31	5.5
	Seitz E.K.		0.04	3.5
	Ford's 'Sterimat'		0.08	—
	'Millipore'		0.07	—
	Unfiltered	Baby hamster kidney C 997	0.60	—
	Seitz E.K.		None detected	—
Eagle's	Unfiltered	Pig kidney C 997	0.54	5.5
	Seitz E.K.		0.27	5.1
	'Millipore'		None detected	3.9
	Unfiltered	Baby hamster kidney C 997	1.9	—
	Seitz E.K.		1.2	—
	'Millipore'		1.9	—
	Unfiltered	Baby hamster kidney O 1	2.0	—
	Seitz E.K.		1.4	—
	'Millipore'		2.0	—

include batches of his filtered media in some of these experiments.

Monolayers of pig kidney cells or baby hamster kidney cells (BHK 21, clone 13) were infected with foot-and-mouth disease virus of type C (strain 997) or type O (strain 1), washed once with the medium to be tested and then incubated at 37° until the cell sheet was removed from the glass by the action of the virus. The yield of virus was usually measured by determining the amount of complement (C') fixed with the homotypic antiserum, but in some experiments the amount of infective virus was also determined. The medium in which the infected cell sheets were incubated was filtered through a Seitz E.K. or Ford's 'Sterimat' asbestos pad or through a cellulose acetate membrane (Millipore Filter Corporation, Bedford, Mass.). In order to standardize conditions, 100 ml. of medium were filtered through an asbestos pad of 5 cm diameter or a membrane filter of 2.5 cm diameter.

The results in Table 1 show clearly that filtration of either phosphate-low or Eagle's medium through a Seitz or Ford's asbestos pad results in a considerable reduction of virus yield in both pig kidney and baby hamster kidney cells. In contrast, filtration of Eagle's medium through a cellulose acetate membrane filter had no effect on the virus yield in baby hamster kidney cells. Virus yields in pig kidney cells incubated in this medium, however, were as low as or even lower than those obtained with Eagle's medium which had been filtered through asbestos. This considerable reduction in virus yield in pig kidney cells was also observed with cellulose acetate filtered medium provided by Mr. House.

That these reductions were due to a toxic factor rather than to the removal of a necessary nutrient was shown in the virus yields obtained when the infected cell sheets were incubated in mixtures containing equal proportions of unfiltered and filtered Eagle's medium (Table 2). Although dilution of the unfiltered Eagle's medium with an equal volume of 0.15 M sodium chloride had only a small effect on virus yield, dilution with an equal volume of filtered medium reduced the yield considerably. By taking successive samples of filtrate from one asbestos pad House showed that the cloning efficiency of baby hamster kidney cells was not reduced by medium which passed through the

pad following adequate washing with the same medium. Similarly, using successive filtrate samples provided by Mr. House, we found that, whereas the medium passing first through the asbestos pad considerably inhibited virus growth, later samples had no inhibitory effect.

The nature of the toxic factor or factors has not been examined. The results illustrate, however, that care must be exercised in the use of filters as a means of sterilizing cell culture solutions which are to be used for virus growth.

## GENETICS

### Interphase Deoxyribonucleic Acid Condensation, Late Deoxyribonucleic Acid Replication, and Gene Inactivation

A FEW years ago, Ohno<sup>1,2</sup> discovered that one of the two X chromosomes of female mammals remains condensed in somatic interphase nuclei, and Park showed that this phenomenon becomes apparent during the first three weeks of embryonic life<sup>3</sup>. Based on these findings and on the mosaicism observed for X-linked factors in female mice, Lyon<sup>4,5</sup> proposed a relationship between DNA condensation and metabolic inactivation of one of the two X chromosomes of females.

In agreement with this idea, it is now known that X chromosomes in excess of one become highly condensed in interphase somatic nuclei during early embryogenesis and produce little phenotypic effect<sup>6</sup>. Furthermore, normal males (XY) and females (XX) as well as individuals with as many as 5 X chromosomes have similar amounts of an X-linked enzyme<sup>6,7</sup>.

A further characteristic of the X chromosome was reported by Taylor<sup>8</sup> and Morishima *et al.*<sup>9</sup> when they found that the X chromosome that forms the sex chromatin body has a characteristic late DNA replication pattern.

An analogy to the heterochromatic X may be presumed for the Y chromosome since it shows positive heteropyknosis in early prophase<sup>1</sup>, has late DNA replication<sup>10,11</sup>, and extra Y chromosomes produce no conspicuous phenotypic effects<sup>11</sup>.

It is noteworthy that out of 22 pairs of autosomes, only three viable trisomies are known: trisomies  $D_1$ , 18 and  $G_1$  (ref. 11). Because of the small number of viable autosomal trisomies and the existence of autosomes with smaller DNA mass than the  $D_1$  and 18 chromosomes, it seems reasonable to assume that a large portion of the DNA of chromosomes  $D_1$ , 18 and  $G_1$  is condensed in somatic interphase nuclei and, therefore, physically unable to produce RNA. Furthermore, due to the multiple phenotypic effects and the lack of conspicuous interphase DNA condensation of the chromosomes involved in the viable autosomal trisomies, it can be again assumed that such autosomes would be less condensed and not as late replicating as the heteropyknotic X.

Work from my laboratory has recently shown that the chromosomes involved in the only three viable autosomal trisomies are largely late replicating ones, although not as much as the heterochromatic X chromosome<sup>12-14</sup>.

Since autosomes other than  $D_1$ , 18 and  $G_1$  have relatively large late DNA-replicating segments, the hypothesis can be extended to predict that autosomal partial trisomies and partial deletions will be found and would correspond to large and mostly late replicating or very small and early replicating chromosome segments. In this direction

Table 2. EFFECT OF MIXING FILTERED AND UNFILTERED EAGLE'S MEDIUM ON THE YIELD OF FOOT-AND-MOUTH DISEASE VIRUS IN PIG KIDNEY AND BABY HAMSTER KIDNEY CELLS

Medium	Cell and virus type	Virus yield (ml. 1/30 C' fixed by 1 ml.)
Eagle's—unfiltered	Pig kidney C 997	0.63
Seitz E.K. filtered	C 997	0.30
unfiltered + Seitz filtered (50 : 50)		0.32
'Millipore' filtered		0.10
unfiltered + 'Millipore' filtered (50 : 50)		0.16
unfiltered + 0.15 M NaCl (50 : 50)		0.55
unfiltered	Baby hamster kidney O 1	2.0
Seitz E.K. filtered		1.5
unfiltered + Seitz filtered (50 : 50)		1.6

it is interesting to know that partial trisomy for a sizable segment of the long arm of a C chromosome<sup>13</sup> is now known to be viable and involves late DNA replicating chromosome segments. Furthermore, deletions of the short arm of a No. 5 (refs. 16 and 17) and No. 18 (ref. 18) chromosomes have been found in the human population and correspond to absent late DNA replicating chromosome segments.

Because all the viable human congenital chromosomal abnormalities so far tested have been found to be composed of late replicating DNA (triploid/diploid individuals and trisomy mosaics for chromosomes other than  $D_1$ , 18 and  $G_1$  have been observed; in these individuals, it is suggested that life is sustained by a sufficient admixture of diploid cells<sup>19</sup>), it is postulated that these chromosomes are not as deleterious as early replicating ones when present in excess or defect, because late replicating DNA may be an expression of complete or partial metabolic gene inactivation<sup>11,20</sup>.

Furthermore, in accordance with the heteropyknotic X, it is suggested that late replicating autosome segments become condensed in somatic interphase nuclei during early embryogenesis.

The possible role of arginine-rich histone in the causation of late replicating DNA and interphase DNA condensation is now being investigated here.

### Induction of Sex-linked Recessive Lethals and Visible Mutations by feeding X-irradiated DNA to *Drosophila melanogaster*

ATTEMPTS to induce genetic changes by chemical means go back to early days of modern genetical research. Even when Muller's<sup>1</sup> discovery of the mutagenic effect of X-rays had opened up a new and exceedingly fruitful field of research, the search for chemical mutagens was not abandoned. In fact, during the last two or three decades, hundreds of chemicals have been tried for their mutagenic effect; however, most of these are highly toxic and are not found free in Nature. The search for a specific mutagen led Gershenson<sup>2,3</sup> to try calf-thymus nucleic acid for its mutagenic effect. Gershenson reared flies upon food to which a large amount of (5 per cent) thymonucleic acid was added and found that a considerable number of the imagoes, derived from the larvae

that had had this food, showed various characteristic abnormalities. When these flies were bred, similar abnormalities were often found among their progeny. A large number of wing-mutations were claimed to have been induced by this treatment and this led him to claim that mutations had been produced *en masse*. Gershenson, employing *ClB*-technique, could not find any increase in the induction of sex-linked-lethals (s.l.l.). Rapoport<sup>4</sup> repeated Gershenson's experiments and he too could not observe any increase in s.l.l. rate. Muller<sup>5</sup> tried both thymonucleic and yeast nucleic acids and did observe some phenotypic abnormalities but again no increase in s.l.l. To quote Muller: "It is hardly conceivable that a variety of types of visible mutations could be induced *en masse* by any agent without there being some appreciable effect on the lethal mutation frequency also". He was therefore of the opinion that there is no indication of either visible or lethal mutations induced by this treatment. On general considerations, one would not expect any harmful or mutagenic effect of the natural DNA, which forms an important part of the food consumed by every living organism. However, the possibility of such mutagenic effect of certain DNA's for certain organisms under given conditions could not be absolutely ruled out.

Other considerations which led me to this investigation were the process of sterilization of food by employing strong doses of penetrating radiations. We know that radiations not only destroy the micro-organisms responsible for the decay processes, they produce certain definite, though not very well understood, changes in the food as well.

The proteins, the sugars and other carbohydrates will undergo changes as a result of direct and indirect action of the radiations. The most important, however, are the nucleoproteins and particularly the deoxyribonucleic acid (DNA) present in every cell nucleus. The DNA, as we know, is a polymer of high molecular weight, consisting of a chain of nucleotides, each nucleotide in turn consisting of a base, a sugar and phosphoric acid. Irradiation of DNA causes strand separation (rupture of the hydrogen bonds) and degradation or depolymerization (rupture of the main chain), in addition to other radiochemical changes. It is assumed that the irradiation products of DNA, denoted here as 'DNA<sub>m</sub>' (without specifying its exact physical and chemical nature at present) when taken orally, might pass through the intestinal wall and circulate in the body. These circulating bits of DNA<sub>m</sub>, on entering the cell-nuclei (by analogy with the action of the viruses) of the germ-cell line or other somatic cells, get incorporated somehow in the genetic apparatus, thus giving new hereditary characteristics to the affected cells; that is to say, inducing mutations. Mutations of the somatic cells might lead to cancerous growths or other abnormalities. Mutations in the germ cells will lead to hereditary changes in the progeny.

It was, therefore, tempting to investigate the radio-mimetic effect of DNA<sub>m</sub>, particularly because DNA is a part of the food, and of every cell-nucleus, of living organisms and is all the time under the influence of ionizing radiations (cosmic-rays and natural and artificial radioactivity, etc.) necessary to induce the desired structural changes. Further, unlike other mutagenic and carcinogenic substances (TEM, nitrogen-mustards, etc.) which are artificially produced and generally speaking artificially introduced into the organisms, and which are highly toxic and foreign to the body, DNA<sub>m</sub> might arise in the body of the organism (DNA + radiations) or may enter the body with food. The possibility of injecting DNA<sub>m</sub> into the organisms is not ruled out either. To my knowledge no investigations showing the mutagenic action of irradiated DNA (DNA<sub>m</sub>) have yet been reported for either *Drosophila melanogaster* or for any other organisms.

The experimental procedure employed to test the above hypothesis was the following. The DNA, in dry powder

form, was irradiated with 100,000 r. (180 keV, 20 m.amp with 2 mm Al filter) of X-rays at the rate of 625 r./min and 450 mg of this was added to about 25 g of the normal culture medium when warm, and mixed thoroughly by stirring with a glass rod. Adult *Drosophila melanogaster* flies (0-4 days old) of the 'Oregon-R' strain were allowed to feed on this medium and lay eggs therein for 10-12 days and were then discarded. The males emerging from the larvae that had had this treated food were tested for the presence of the s.l.l. by employing Muller's *CIB*-technique as shown below:

♂	♀
P: $l_m/Y$	$X\ CIB/v$
F <sub>1</sub> : $v/Y$	$X\ CIB/l_m$
F <sub>2</sub> : $l_m/Y +$	$CIB/v$
$CIB/Y +$	$l_m/v$

where  $v$  stands for vermilion and  $l_m$  denotes the lethal factor induced in the X-chromosome of the male under test through the action of DNA<sub>m</sub>. Each  $l_m/Y$  test male (0-2 days old) was mated with 2-3  $CIB/v$  females and a number of such cultures started. As the number of test males was large, some multi-male cultures were started as well. In F<sub>1</sub> the  $CIB/l_m$  females were selected and mated singly to  $v/Y$  brothers (8-10 such cultures per test-male). In F<sub>2</sub> these cultures were checked for the presence of males. The cultures containing at least 30 females and no males were taken to contain the lethal factor  $l_m$ . As we were not looking for the visible mutations, not all the cultures were checked thoroughly. However, the cultures containing flies with conspicuous features could not escape unnoticed. A check of these cultures led to the detection of a number of visible mutations of the wings, eyes, etc., in addition to a number of flies with gross morphological abnormalities.

In order to eliminate any possibility of the non-irradiated DNA being mutagenic or having any mutagenic contaminations, a parallel experiment was performed with non-irradiated DNA. The same amount (450 mg) of non-irradiated DNA was added to the culture medium as before and 0-4 days old 'Oregon-R' flies allowed to feed on it. The rest of the procedure was exactly the same. The experiments were performed at a temperature of 22-24°C.

Out of 635 DNA<sub>m</sub> cultures checked, 36 were without males, giving an s.l.l. rate of about 5.7 per cent as compared with 486 DNA-cultures where none was without males (s.l.l. rate 0.0 per cent). In addition, no conspicuous visible mutations or flies with morphological abnormalities were detected.

These results definitely establish the mutagenic effect of the irradiated DNA (DNA<sub>m</sub>) and the non-mutagenic nature of the normal DNA in the present case. Taking the spontaneous mutation rate to be 0.17 per cent, (ref. 6) for the sake of comparison, the present experiment shows a 32-fold increase over the spontaneous rate; this would correspond to a direct exposure of the spermatocytes to about 2,000 r. of X-rays.

It may not be inappropriate to mention the results obtained by Swaminathan *et al.*<sup>7</sup> by feeding *Drosophila melanogaster* on irradiated 'complex medium'. These results might be explained in the light of the effect observed by us; however, it may be remarked that irradiation of the complex medium results in much more complicated changes of the medium. Stable or meta-stable mutagenic compounds (H<sub>2</sub>O<sub>2</sub>, aldehydes, etc.) may be produced as a result of direct and indirect action of the radiations on the components of the employed medium (water, sugar and other carbohydrates, proteins and DNA, etc.), and one could not attribute the mutagenic effect to any definite mechanism or to any definite mutagens produced as a result of irradiation. In our case, however, it is definitely the DNA<sub>m</sub> and this alone that is acting as mutagen.

Due to the general importance of the part played by DNA and the ionizing radiations in the evolutionary,

biochemical and genetical processes it is thought worthwhile to publish this preliminary report. Further, if our conclusions are substantiated, one might infer that the sterilization of food by using high doses of ionizing radiations is not desirable. In addition, it may be mentioned here that in DNA<sub>m</sub> we have a natural mutagenic substance with all the implied potentialities. Other experiments to verify these results are in progress and will be reported in detail elsewhere.

I thank Prof. F. Mainx for advice and facilities, and Prof. H. J. Muller and Prof. C. Auerbach for their constructive criticism. I also thank Mayoly-Spindler Laboratories, Rueil-Malmaison, France, for the DNA used in this work.

### Giant Chromosomes in Protozoa

So far as we know polytene chromosomes have been previously observed only as typical structures in the salivary gland cells of Diptera, and in certain plant cells. By using orcein we have been able to demonstrate such structures (Fig. 1) in the macronuclear anlage of *Stylonychia muscorum* Kahl (a hypotrichous ciliate). According to our preliminary observations, there are in this species 50-60 giant chromosomes which show a great diversity in both size and banding. They range from 15μ to 55μ in length, and from 0.8μ to 2.5μ in width.

We hope to improve the method in order to explore such chromosomes in other ciliate species, principally *Paramecium aurelia*, *P. bursaria* and *Euplotes* sp., which have been more widely investigated in terms of their genetics and macronuclear behaviour.

If giant chromosomes are generally characteristic of ciliates, they will provide a more exact basis for the

Fig. 1. Some giant chromosomes from the macronuclear anlage of *Stylonychia muscorum*

understanding of the nature and behaviour of the macro-nucleus and a new approach to the genetics and taxonomy of this group of Protozoa.

### Genetic Control of the Caffeine Content of Coffee

CAFFEINE is one of the main constituents of the coffee bean. In spite of the existence of a limited but expanding market for decaffeinated coffee, most people still seem to prefer the normal product with caffeine. So important is the caffeine in coffee that Chevalier<sup>1</sup> separated all 18 coffee species of Madagascar and Mascarene Islands into a special section *Mascarocoffea*, on the basis of the presence, or absence, of caffeine. On the other hand, the *Eucoffea* section, which includes the cultivated coffee species, comprises only species with caffeine.

Caffeine content in coffee has been extensively considered by various authors<sup>2</sup> and found to vary between and within species. A series of chemical analyses has also been run in Campinas with seed samples of plants belonging to the main cultivars and varieties of *Coffea arabica*. Reasonable variations were found, particularly among the 'Mundo Novo' strains, indicating the possibility of isolating coffee selections with different levels of this alkaloid<sup>3</sup>.

Preliminary information from another series of *Coffea arabica*<sup>4</sup> obtained in Campinas has indicated that 'Laurina' has about half as much caffeine as 'Typica'. The 'Laurina' variety possibly originated in the Reunion Islands (Mascarene Islands) or was introduced to this island many years ago from Ethiopia or from the Yemen<sup>1,5</sup>. The plants have a tight growth, small leaves and pear-shaped fruits containing two small pointed seeds. The same type of seeds is found in some other non-cultivated diploid species belonging to different sections.

Genetic analysis of plants having the 'Laurina' characteristics revealed that this phenotype is controlled by a recessive pair of alleles *lr lr*, with a strong pleiotropic effect. Other varieties, except 'Mokka', are homozygous for the normal allele *Lr*. The 'Mokka' variety as described by Cramer<sup>6</sup> differs from the standard 'Typica' by the presence of both *mo* and *lr* alleles in homozygous condition, and coffee trees with the genetic constitution *LrLrmo mo* are quite similar to 'Mokka', differing only in the shape and height of the plants. This form has been called 'Kona' in some coffee collections.

In order to determine if the *lr* allele was responsible for the drastic reduction in the caffeine content, an experimental trial was made (randomized block with four replications) with samples taken from nine varieties and cultivars shown in Table 1. The 'Typica' variety was used as a standard. The *L.S.D.* at one per cent level indicated that only the Mokka-Maragogipe recombinant had a higher caffeine content than 'Typica'. The three varieties having *lr lr* alleles have a very low amount of caffeine. The Duncan test, applied to the data of this experiment, permitted the grouping of the varieties in five classes, as shown in Table 1. Among the entries having the *lr lr* alleles, the form 'Laurina' (*tt lrlr MoMo mgmg XcXc*) had a significantly lower caffeine content than the other group formed by the recombinants *tt lrlr momo mgmg XcXc* and *tt lrlr MoMo MgMg XcXc*. Samples of 'Bourbon Amarelo' (*tt LrLr MoMo mgmg xcxc*) and 'Bourbon Vermelho' (*tt LrLr MoMo mgmg XcXc*) form the third and fourth groups, while the other four varieties have a high caffeine content.

This information indicates that the presence of the *lr lr* alleles is responsible for a drastic reduction in the

Table 1. AVERAGE WEIGHT OF CAFFEINE EXPRESSED IN MG PER 10 G OF GREEN COFFEE BEAN, FROM SAMPLES TAKEN FROM CAMPINAS COLLECTION IN 1963, AND GROUPED ACCORDING TO THE DUNCAN TEST

Group	Variety	Genetic constitution	Caffeine (mg/10 g)
1	Laurina	<i>tt lrlr MoMo mgmg XcXc</i>	60.5
2	Mokka	<i>tt lrlr momo mgmg XcXc</i>	77.8
	Laurina-Maragogipe	<i>tt (?) lrlr MoMo MgMg XcXc</i>	79.2
3	Bourbon Amarelo	<i>tt LrLr MoMo mgmg xcxc</i>	109.9
4	Bourbon Vermelho	<i>tt LrLr MoMo mgmg XcXc</i>	113.7
	Typica	<i>TT LrLr MoMo mgmg XcXc</i>	122.7
5	Kona	<i>TT (?) LrLr momo mgmg XcXc</i>	123.1
	Maragogipe	<i>TT LrLr MoMo MgMg XcXc</i>	123.9
	Mokka-Maragogipe	<i>TT (?) LrLr momo MgMg XcXc</i>	127.9

*L.S.D.* = 3.58 mg

*C.V.* = 1.74 per cent

caffeine content and that the *xanthocarpa* (*xc*) and *bourbon* (*t*) factors also have a slight tendency to diminish the caffeine. The *maragogipe* (*Mg*) and the *mokka* (*mo*) alleles, conversely, seem to increase the caffeine content.

At present there is no information about which steps in the chain of reactions leading to caffeine formation and accumulation in the coffee bean are affected by the *lr* and other alleles mentioned.

We thank Dr. Sherman J. Leonard for advice.

### SOIL SCIENCE

#### Circulation of Water in Soil under a Temperature Gradient

SEVERAL workers (for example Gurr *et al.*<sup>1</sup>, Hutcheon<sup>2</sup>) have suggested that, when a temperature gradient is applied to a uniform closed soil column, a circulatory system is set up, and that any eventual steady moisture distribution is actually a dynamic balance of opposing fluxes, predominantly vapour from hot to cold, and predominantly liquid from cold to hot. In this communication we show that, at equilibrium, a static system cannot exist, and confirm experimentally the existence of a circulatory system.

In a porous material:

$$\ln h = g\Phi/RT = g(\psi + \pi)/RT \quad (1)$$

where  $h$  = relative humidity,  $g$  = acceleration due to gravity ( $\text{cm/s}^2$ ),  $R$  = gas constant for water vapour ( $\text{erg/g deg}$ ),  $T$  = temperature ( $\text{deg K}$ ), and  $\Phi$  is the total water potential ( $\text{cm water}$ ) comprising matric ( $\psi$ ) and osmotic ( $\pi$ ) components.

Also, for water vapour, over a small temperature-range:

$$\ln \rho_s = \alpha + \beta T' \quad (2)$$

where  $\rho_s$  ( $\text{g/cm}^3$ ) is the saturated vapour density at  $T'$  K, and  $\alpha$  and  $\beta$  are positive constants.

At any point, the vapour density  $\rho = h\rho_s$ , so differentiating and using (1) and (2), the vapour density change along a column subjected to a temperature gradient must satisfy:

$$\frac{1}{\rho} \delta \rho = \frac{g}{RT} \left( \delta \psi - \frac{\psi}{T} \delta T \right) + \frac{g}{RT} \left( \delta \pi - \frac{\pi}{T} \delta T \right) + \beta \delta T \quad (3)$$

For static equilibrium, the fluxes of liquid, vapour and solute must all be zero simultaneously, that is,  $\delta \psi$ ,  $\delta \rho$  and  $\delta \pi$  must all be zero, and therefore:

$$0 = \delta T (\beta - g\Phi/RT^2)$$

Fig. 1. Final liquid distributions. Volumetric liquid content plotted against distance from the cold end of the soil columns.  $\circ$ , non-saline;  $\bullet$ , saline;  $\text{—}$ , initial mean value (horizontal line) and standard deviation (vertical bar)

Fig. 2. Final salt distributions: (a) ratio mmole NaCl/g  $\text{H}_2\text{O}$ , and (b) ratio mmole NaCl/100 g soil as functions of distance from cold end of columns.  $\circ$ , sand;  $\bullet$ , soil

Fig. 3. Final temperature distributions:  $\circ$ , non-saline;  $\bullet$ , saline

which is impossible because  $\Phi$  is always negative or zero. Thus simultaneous static equilibrium of temperature, vapour, liquid and solutes cannot be achieved.

Columns, 10 cm length and 3.8 cm diameter, built from 1-cm sections of 'Perspex' tube, were uniformly packed with soil, saturated, drained at  $\psi = -100$  cm, and sealed with a vacuum sealing compound. The columns, well insulated, were screwed to thick brass plates in intimate contact with constant-temperature baths at 17.6 and 27.8°C.

Two inert porous media were used: (1) a fine white sand, of density 2.65 g/cm<sup>3</sup> and porosity 0.39; (2) ignited 0.5–1 mm aggregates of local top-soil, of density 2.54 g/cm<sup>3</sup> and porosity 0.66. In each experiment there were four replicate columns, two each with water and strong sodium chloride solution. Temperatures were measured with copper-constantan thermocouples inserted at 1 cm intervals.

After 12 days the columns were sectioned, the liquid distribution found by oven-drying, and the salt distribution estimated conductometrically. The initial uniformity of salt and liquid distributions within the columns was tested in the same way on other replicates not subjected to a temperature gradient.

Fig. 1 shows the final liquid distributions, and Fig. 2 the final salt distributions; 2 (a) the ratio mmole NaCl/g water, and 2 (b) the ratio mmole NaCl/100 g soil. Each point is the mean of duplicates, and the mean value and initial deviation for the column are indicated by each line. Temperature distributions in the saline and non-saline columns differed (Fig. 3): the results for sand are consistent with thermal conductivity differences caused by liquid content differences.

For both materials there was, as expected, net water movement from hot to cold, the movement being greater in the absence of salt, possibly because the salt acted as a sink for water vapour at the hot end. In the sand there was little net transfer of water in the presence of salt.

Fig. 2 is of more interest. When a temperature gradient is applied along a column in which water and salt are initially uniformly distributed, two kinds of transfer are

possible. If water moves only as vapour, the ratio mmole salt/g soil will remain constant, but the ratio mmole salt/g water will increase in regions where evaporation occurs and decrease in regions of condensation. Conversely, if water moves only as liquid, the ratio mmole salt/g water will remain constant, but that of mmole salt/g soil will increase in the regions to which the liquid flows and decrease in those from which it flows. The results of Fig. 2 are thus consistent with a vapour flux moving from hot to cold, and a return liquid flux from cold to hot—a circulatory system.

### Changes in Phosphate Potential on Re-wetting Air-dry Soil

WHEN soil is suspended in dilute calcium chloride solution the calcium dihydrogen phosphate potential ( $pH_2PO_4 + \frac{1}{2}pCa$ ) varies with the soil:solution ratio<sup>1</sup> and with the period for which the soil is in suspension<sup>2</sup>. Air-drying and re-wetting also affect the phosphate potential<sup>3</sup>. Laboratory measurements lacking precision will help little in predicting phosphate availability in field soils.

In Rhodesia arable top soils are always dry after the almost rainless winter, so only the changes on re-wetting were examined here. Using a soil:solution ratio of 1:2, a sandy loam derived from micaceous schist was equilibrated in 0.01 M  $CaCl_2$  for 1 h at 21° C after the following treatments: shaken by wrist-action in stoppered bottles (soil:solution = 1:2), or incubated at field capacity (15 per cent moisture) at either 21° or 35° C, each treatment being continued for different periods up to 12 days, with and without adding 120  $\mu$ mole  $KH_2PO_4$ /100 g soil. Changes due to microbial action during the final 1 h equilibration were probably negligible<sup>4</sup>. pH was measured in the suspensions, and the concentrations of P and Ca + Mg (expressed as Ca) in the filtrates; activities were calculated by the Debye-Hückel equation (using Aslyng's<sup>5</sup> correction for  $pH_2PO_4$ ). Total mineral nitrogen was determined in similarly treated samples.

Fig. 1 shows that in all treatments  $pH_2PO_4 + \frac{1}{2}pCa$  initially increased with time, that is, soluble phosphate decreased. On moistening soil to field capacity the phosphate potential approached a constant value after 4–5 days, but in suspension it changed more, over a longer period. This may be due to microbial action<sup>6</sup>, but the mineral nitrogen content changed more at field capacity than in suspension (Table 1); incubation at 35° gave more

Fig. 1. Changes in phosphate potential with time of incubation.  $\Delta$ , +P (field capacity, 21°); +P (suspension, 21°);  $\bullet$ , -P (field capacity, 35°);  $\circ$ , -P (field capacity, 21°);  $\times$ , -P (suspension, 21°)

mineral nitrogen than at 21° C, but had little effect on the phosphate potential. If the effects of microbial action differ between soils in suspension and at field capacity, the latter is closer to conditions in field soils.

Larsen and Widdowson<sup>1</sup> suggested that increasing soil:solution ratios decreased pH and the phosphate potential in soil suspensions because more  $CO_2$  was produced. Presumably more  $CO_2$  is produced after longer periods in suspension, but in the present work pH and phosphate potential (Table 1 and Fig. 1) both increased with longer suspension, more so than with aerobic incubation at field capacity.

Another sandy soil was incubated at field capacity for 7 days at 21° C, then equilibrated in 0.01 M  $CaCl_2$  for 1 h (21° C), using 10, 38, 138 or 470 g soil/l. Table 2 shows that pH and phosphate potential decreased with increasing soil:solution ratio, as reported by Larsen and Widdowson<sup>1</sup>, although changes in  $CO_2$ -pressure must have been negligible<sup>3</sup>. The effects of soil:solution ratio were almost certainly due to the soil being changed more from its original state in attaining equilibrium at smaller soil:solution ratios.

Where there are distinct dry and rainy seasons, so that field soils are naturally air-dried before cropping, moistening samples to field capacity at room temperature for at least 4 days (7 days is convenient for routine measurements) before equilibrating for 1 h in suspension gives steady values of the phosphate potential (or of phosphate concentration, if this is preferred<sup>5</sup>). These may enable the relationships between soil solution measurements and plant composition to be tested more reliably than by methods previously proposed.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, January 18

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Council Room of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Dr. W. E. Knowles Middleton: "The Nature of Clouds".

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. J. F. Lovett: "Analysis of Lindane and Its Formulations".

UNIVERSITY OF LONDON (in the Botany Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. von Wettstein (University of Copenhagen): "Macromolecular Physiology of Plastids".\*

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 7 p.m.—Dr. A. E. A. Werner: "The Scientific Examination of Paintings and Antiquities" (Ninth Annual Ladies Evening).

## Tuesday, January 19

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. A. A. Fulton and Mr. L. H. Dickerson: "Design and Construction Features of Hydro-Electric Dams Built in Scotland Since 1945".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Performance of Hill-Climbing Systems—The Gradient Estimation Problem".

QUEEN ELIZABETH COLLEGE (University of London) (at Campden Hill Road, London, W.8), at 5.30 p.m.—Prof. J. Edelman: "The Development of Experimental Botany" (Inaugural Lecture).

ROYAL AERONAUTICAL SOCIETY (joint meeting with the Institution of Electrical Engineers, at 4 Hamilton Place, London, W.1), at 6 p.m.—Discussion Meeting on "The Development of Dependable Fire Warning Systems in Aircraft" opened by Mr. J. R. Stevens.

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION AND EDUCATION AND TRAINING GROUP (at the Chamber of Commerce, 75 Harborne Road, Edgbaston, Birmingham 15), at 6.30 p.m.—Discussion on "The Motor Industry: Future Requirements for Education and Training".

PLASTICS INSTITUTE, LONDON SECTION ENGINEERING SUB-GROUP (at the Coachmakers Arms, 88 Marylebone Lane, London, W.1), at 6.30 p.m.—Forum—Mr. J. H. Ellis: "Equipment for Finishing and Decorating Plastics: Hot Foil Stamping Machinery". Mr. J. Colterrell: "Silk Screening Equipment". Mr. A. Coates: "Deflashing of Mouldings".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Slough College Scientific Society, at Slough College, William Street, Slough), at 7.30 p.m.—Mr. T. Green: "Colour".

## Wednesday, January 20

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—The Rev. A. Q. Morton: "The Authorship of the Pauline Epistles—a Scientific Approach".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. W. D. Humpage and Mr. B. Stott: "Effect of Auto-Reclosing Circuit-Breakers on Transient Stability in Extra-High-Voltage Transmission Systems".

UNIVERSITY OF LONDON (in the Botany Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. von Wettstein (University of Copenhagen): "On the Genetic Control of Chloroplast Structures and Function".\*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, ELECTRO-ACOUSTICS GROUP (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Dr. B. K. Gazey and Dr. J. C. Morris: "Acoustic Communication Underwater".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. H. L. Willett: "New Safety Techniques in Mining" (Cadman Memorial Lecture).

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S.W.7), at 6 p.m.—Mr. R. T. Lovelock: "A Central Recording Station for a Climatic Laboratory".

INSTITUTE OF INFORMATION SCIENTISTS (at State House, High Holborn, London, W.C.1), at 6.15 p.m.—Mr. E. Martindale: "Technical Information Services and D.S.I.R.".\*

INSTITUTION OF MECHANICAL ENGINEERS, GRADUATES' AND STUDENTS' SECTION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.30 p.m.—Mr. D. J. Veasey: "L.T.E. Victoria Line Extension".

OIL AND COLOUR CHEMISTS' ASSOCIATION, STUDENT GROUP (at the London College of Printing, Elephant and Castle, London, S.E.1), at 7 p.m.—Meeting on "Working Properties of Ink—Rheology and Tack".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Dr. David K. Brooks: "Water and Electroclyte Metabolism".

ASSOCIATION OF THE WILLIAM PENGELLY CAVE RESEARCH CENTRE in conjunction with Imperial College Caving Club (in the Physics Department, Imperial College, Prince Consort Road, London, S.W.7), at 8 p.m.—Mr. David Attenborough and Mr. George Black: "Caves in Danger".\*

## Thursday, January 21

UNIVERSITY COLLEGE, LONDON (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. W. J. D. Jones: "Growing Whiskers—the Development of High Strength Materials".\*

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 4 p.m.—Discussion on "Keeping the Engineer Up-to-Date and Finding Information".

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Pierre Oy: "Sampling of Ores and Metallurgical Products During Continuous Transport"; Dr. V. L. Bosazza: "The Formation of Malachite and Chrysocolla from Chalcopryrite in Rocks of the Bushman Mine Series, Northern Bechuanaland Protectorate".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Meeting on "Electron Microscopy in Relation to Taxonomy in Unicellular Algae" with contributions by Mrs. Katharine Harris, Mr. R. Ross and Prof. Irene Mantou, F.R.S.

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. H. T. Croft: "9 Points and 7 Points in 3 Dimensions".

INSTITUTION OF CIVIL ENGINEERS, HYDROLOGICAL GROUP (at Great George Street, Westminster, London, W.1), at 5.30 p.m.—Informal Discussion on "Hydro-Geology and Its Part in the Hydrological Cycle" introduced by Dr. S. Buchan.

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 6 p.m.—Discussion Meeting on "The Current Procedure for Advising the Government on Aviation Policy" opened by Sir George Gardner.

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Dr. M. J. Dunblaton and Mr. P. F. Sherwood: "The Use of Lime and Mixtures of Lime and Pulverized Fuel Ash for Soil Stabilization".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. L. J. Bruce-Chwatt: "Malaria Research for Malaria Eradication".

## Friday, January 22

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.E./I.E.R.E. MEDICAL ELECTRONICS GROUP (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p.m.—Discussion on "The Direct Recording of Biological Signals".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Colloquium on "Network Analysis".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION, CAMBRIDGE SUB-SECTION (joint meeting with the Cambridge University Chemical Society, at the University Chemical Laboratory, Lensfield Road, Cambridge), at 8.30 p.m.—Dr. T. M. Sugden, F.R.S.: "Some Aspects of the Chemistry of Flames".

## Saturday, January 23

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Prof. W. F. Grimes: "The Temple of Mithras in Walbrook".\*

## Monday, January 25

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.E./I.E.R.E. COMPUTER GROUPS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 10.30 a.m.—Colloquium on "Logic Circuits".

UNIVERSITY COLLEGE, LONDON (in the Botany Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. P. N. Magee: "The Biochemical Pathology of Intracellular Alkylation Reactions".\*

UNIVERSITY OF LONDON (in the Physiology Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. H. Hubel (Harvard Medical School): "The Eye, The Brain and Perception" (Further lectures on January 27 and 29).\*

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Problem of Obtaining Training Places for Six-Month Sandwich Course Students".

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Mr. J. Hardwood: "Flame Retardant Processes".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

COMPUTING ASSISTANT (with a good honours degree in mathematics or in a pure or applied science, and preferably some experience with large scale computing machinery) IN THE ELECTRONIC COMPUTING LABORATORY—The Registrar, The University, Leeds, 2 (January 22).

ASSISTANT LECTURER or LECTURER (preferably with an interest in ethics and perception) IN THE DEPARTMENT OF PHILOSOPHY—The Secretary, University College of Swansea, Singleton Park, Swansea (January 23).

DEMONSTRATOR IN THE DEPARTMENT OF PSYCHOLOGY—The Registrar, The University, Liverpool, 3. Quoting Ref. CV/391 (January 23).

LECTURER or ASSISTANT LECTURER IN SOCIOLOGY—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (January 25).

LECTURER (with a first degree in physics, engineering or mathematics and appropriate postgraduate experience) IN APPLIED PHYSICAL SCIENCE IN THE DEPARTMENT OF PHYSICS—The Registrar (Room 22, O.R.B.), The University, Reading (January 25).

LECTURERS (with field work experience, preferably in the United Kingdom as well as overseas) IN THE DEPARTMENT OF SOCIAL ANTHROPOLOGY—The Secretary, The University, Edinburgh (January 28).

LECTURERS or ASSISTANT LECTURERS (2) IN SOCIOLOGY—The Registrar, The University, Hull (January 29).

CHAIR OF APPLIED MATHEMATICS—The Registrar, University College of Swansea, Singleton Park, Swansea (January 30).

LECTURER or ASSISTANT LECTURER IN APPLIED MATHEMATICS—The Registrar, University College of Swansea, Singleton Park, Swansea (January 30).

LECTURER or ASSISTANT LECTURER IN INORGANIC CHEMISTRY; and a LECTURER or ASSISTANT LECTURER IN PHYSICAL CHEMISTRY—The Secretary, The University, Aberdeen (January 30).

LECTURER or ASSISTANT LECTURER IN PURE MATHEMATICS—The Secretary, University College of Swansea, Singleton Park, Swansea (January 30).  
LECTURER or ASSISTANT LECTURER (suitably qualified candidate in either experimental or theoretical physics) IN PHYSICS—The Registrar, University College of Swansea, Singleton Park, Swansea (January 30).

LECTURER (preferably with experience in neurophysiology) IN THE DEPARTMENT OF PHYSIOLOGY—The Secretary, The University, Aberdeen (January 30).

LECTURER (with a good honours geography degree and preferably a Doctorate in the field of physical geography emphasizing climatology) IN GEOGRAPHY—The Secretary, The University, Edinburgh (January 30).

ASSOCIATE or ASSISTANT PROFESSOR (preferably with qualifications and experience in modern mathematics and procedures) OF MATHEMATICS—The Secretary, University of Guyana, P.O. Box 841, Georgetown, British Guiana (January 31).

CHAIR OF GEOGRAPHY at Fourah Bay College, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (January 31).

LECTURER or ASSISTANT LECTURER IN PHYSIOLOGY at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (January 31).

RESEARCH ASSISTANT (with a good honours degree, preferably in physics or chemical engineering, and a special interest in particle mechanics, fluid dynamics or rheology) for a Nuffield Foundation project dealing with particle/fluid flow in model systems—The Registrar, The University, Nottingham (January 31).

LECTURER or ASSISTANT LECTURER (with an honours degree in a biological subject or in physiology) IN BIOLOGICAL OCEANOGRAPHY; and a LECTURER or ASSISTANT LECTURER (with an honours degree in mathematics, electronics or a physical science) IN PHYSICAL OCEANOGRAPHY—The Deputy Secretary, The University, Southampton (February 1).

LECTURER IN PURE MATHEMATICS—The Registrar and Secretary, Old Shire Hall, University of Durham (February 5).

DIRECTOR OF THE UNIVERSITY OF SHEFFIELD INSTITUTE OF EDUCATION—The Registrar, The University, Sheffield, 10 (February 6).

LECTURER, ASSISTANT LECTURER or TERMINABLE LECTURER (medically qualified or with a good honours degree in chemistry or biochemistry) IN THE DEPARTMENT OF CHEMICAL PATHOLOGY—The Secretary, The University, Aberdeen (February 6).

WEST RIDING CHAIR OF MICROBIOLOGY—The Registrar, The University, Sheffield (February 6).

LECTURER and an ASSISTANT LECTURER (with a good honours degree in physiology or biochemistry, or a medical qualification) IN THE DEPARTMENT OF PHYSIOLOGY—The Registrar, The University, Manchester, 13 (February 10).

SENIOR LECTURER or LECTURER IN AGRICULTURAL BOTANY at Ahmadu Bello University, Northern Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (February 10).

LECTURER IN PHYSICS at the University of Otago, Dunedin, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, February 15).

ASSISTANT LECTURERS IN PHYSICS—The Secretary, The Queen's University, Belfast, Northern Ireland (February 20).

SENIOR LECTURER or LECTURER (with an interest in plant taxonomy, morphology or physiology) IN BOTANY at Ahmadu Bello University, Northern Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (February 20).

EXPERIMENTAL OFFICER (with a degree, Graduateship of the Royal Institute of Chemistry or of the Institute of Physics, or at least a Higher National Certificate) IN MASS SPECTROSCOPY IN THE DEPARTMENT OF CHEMISTRY, to maintain and operate a high resolution mass spectrometer as a service to the department, and in due course help in the interpretation of the spectra obtained—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (February 21).

SENIOR DEMONSTRATOR IN PHYSICAL CHEMISTRY—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (February 21).

LECTURER IN GEOLOGY at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, February 22).

VIROLOGIST IN THE DIVISION OF IMMUNOLOGICAL PRODUCTS CONTROL at Hampstead—The Director, National Institute for Medical Research, Mill Hill, London, N.W.7 (March 20).

LIBRARY ASSISTANT (young science graduate) IN THE NEW BIOCHEMISTRY LIBRARY—The Secretary, Biochemistry Department, Imperial College of Science and Technology, London, S.W.7.

MICROBIOLOGIST (national of the United Kingdom or the Republic of Ireland, with a B.Sc. and experience in either microbiology or mycology) in Nigeria, to carry out research on microbiology of stored food products in the south of Nigeria—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC.213/130/61.

PHYSICS or ELECTRONICS ENGINEER (with a first- or second-class honours degree) IN THE PHYSICS DEPARTMENT to assist in the development of techniques associated with the automatic analysis and display of data from clinical scintillation scanners—The Deputy Secretary, St. George's Hospital, Hyde Park Corner, London, S.W.1.

water supplies by the suppression of adverse facts and research, by misleading statements and by exaggerated claims.) Pp. 36. (Thorpe End, Almondbury, Huddersfield: Mrs. W. M. Sykes, Hon. Secretary, National Pure Water Association, 1964.) 2s. 6d. [2511]

# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

**AUTOMATIC** interchange of up to 4 sample and 4 reference cells

**AUTOMATIC** re-cycling over any preselected wavelength range

**AUTOMATIC** recordings at predetermined time intervals.

*Please send for descriptive brochure*

*Save operator time, increase speed and efficiency with Unicam automation for:*

ENZYME REACTION RATES

LIQUID COLUMN CHROMATOGRAPHY

ALL ROUTINE ULTRAVIOLET AND  
VISIBLE SPECTROSCOPY

# DIFCO

*Microbiological  
reagents  
and media*

**delivered  
to your bench quickly**

Hundreds of different products in the complete Difco range are kept in stock ready to be on your bench without delay. We shall always be pleased to obtain other items specially to order.

Speed, convenience, reliability . . . and remember that Difco offer the only *complete* line of culture media available in U.K. Please send for the latest literature concerning your special interests.

**complete  
laboratory  
service**

## BCM 200 REFRACTORY CUTTING MACHINE

**HIGH SPEED PRECISION CUTTING  
OF REFRACTORIES,  
SEMICONDUCTORS AND CERAMICS**

- Cutting Disc Diamond Impregnated 12" dia.  
Max. depth of cut  $3\frac{1}{2}$ ".
- Table mounted on vee guide rollers fitted with  
needle roller journal and thrust bearings.
- Area 11" x 17", with tee slots for clamping.
- Mitre rest and work clamp fitted to table.
- Spindle fitted with taper roller bearings.
- Fully protected from abrasive sludge.
- Vibration free drive powered by  $1\frac{1}{2}$  horse  
power motor. All electrics totally enclosed  
in pedestal.
- Coolant mainwater or soluble oil.  
Finish Grey Stove Enamel.

**CUTROCK ENGINEERING CO. LTD.,**

Telephone: FINCHLEY 5978

## A MATTER OF SCIENTIFIC PRIORITIES

THE seventeenth annual report of the Advisory Council on Scientific Policy covers the year 1963-64\*. It is the last which will appear over the signature of Lord Todd as chairman and also the last to be submitted from the Advisory Council in its present form. In character and in calibre it fully matches the outstanding report submitted for the year 1962-63 (*Nature*, 200, 1133; 1963). The brief review of some major changes in the general environment of science during the life of the Advisory Council and of some achievements of the Council further demonstrate that its successor and the new arrangements will be hard pressed to match, let alone improve on, the efforts of the Council. Moreover, the topics selected for special comment in this report not only illustrate the soundness of the Advisory Council's judgment but also direct attention to one or two matters which have received insufficient attention in the new arrangements, at least up to the present time.

At its establishment the Council faced four main issues and, with the exception of the first, all face the Minister of Technology and the Secretary of State for Education and Science and their advisers to-day. Even the first, in a different form, now faces those and other Ministers, and indeed has been given as a specific reason for establishing the Ministry of Technology. The problems uncovered by the Advisory Council in seeking to recommend the appropriate form that Britain's research effort should take to achieve a maximum increase in national productivity during the decade 1947-57 are still largely with us, nor could it be held that the place of science in Government or the operation of Britain's scientific organization has yet been determined. For all the increase in the number of scientific advisers in the civil departments, the question of the mechanism of scientific advice and the location of research stations is unresolved. The Trend Committee was undecided and the decisions so far taken by the present Government tend to be inconsistent and show no clear pattern.

Likewise, the fourth major task of the original Advisory Council, that of continuous enquiry into the long-term development of Britain's scientific manpower and scientific resources, is a major preoccupation of any Government. While the Committee on Scientific Manpower, which was set up by the Advisory Council, is to continue, insufficient thought appears as yet to have been given to the implications in this task of the establishment of separate Ministries for Technology and for Education and Science. Only a brief section in the present report deals with higher education and scientific manpower, but that brief section stresses two points which have been neglected. The first is the question of postgraduate training and research, and in this context the Council's Committee on Scientific Manpower is at present surveying existing postgraduate courses in technology. The second is the matter of the supply of technicians, a survey of which is being combined with the triennial survey of scientific and technological manpower, to be made by the same Committee in 1965.

\* Annual Report of the Advisory Council on Scientific Policy, 1963-1964. Pp. vi+48. (Cmd. 2538.) (London: H.M.S.O., 1964.) 4s. net. See also p. 347 of this issue of *Nature*.

A related question is that of the status of technology, which is discussed at some length in the light of the findings of a Committee set up in 1963 under the Office of the Minister for Science to consider what might be done to create a climate of opinion more favourable to technology, and so to improve the quality of those entering on technological education. The findings and recommendations of this interdepartmental Committee are appended to the Council's report, and in general the Council agrees with the Committee's conclusions. It does not think, however, that the superior prestige attached in Britain to science as compared with technology is simply a matter of academic prestige. There also appears to be a widely held public attitude that a career in industry is socially unattractive, and the Committee may have over-estimated the significance of the fact that university entrants have not been taught technology at school, and that potential technologists are taught at school by scientists.

Nevertheless, the Council accepts the Committee's recommendation that all possible encouragement should be given to developing contacts between science teachers, the engineering profession and industry; that careers advisers should be approached by means of conferences and literature, and that careers literature for pupils should stress the national importance and intellectual interest of technology as a career; and that the introduction into the teaching of physics and mathematics of experiments illustrating the application of basic physical principles in technology should be further encouraged. The Advisory Council, however, insists that schools must not be diverted from their primary function of providing potential technologists, no less than others, with a broad foundation of knowledge as a basis for their subsequent careers. Again, while agreeing with the Committee on the value of sandwich courses, the Advisory Council thinks that conversion of existing university first-degree courses into sandwich courses is unlikely to improve either the quality of entrants to schools of technology or overall recruitment. While previous industrial experience should not be an absolute requirement for entry to university schools of technology, such experience is valuable, and such students, as well as prospective students of science, should be encouraged to acquire it. Strong support is also given to the Committee's proposals for strengthening the links between industry and the teaching staffs of universities and colleges of technology, including increased use, as part-time teachers, of men holding posts in industry.

The Advisory Council stresses particularly the opportunities for more flexibility in courses which the present expansion of higher education offers. Moreover, it notes with approval that the Committee recommends flexible arrangements to allow students to change their course of study from science to technology, if necessary, with extension of maintenance grant. The desirability of such flexibility has already been emphasized by the University Grants Committee. While, however, the Advisory Council recognizes a need for improved training of graduates by industry, it does not think that

the more progressive firms are likely to share the inter-departmental Committee's doubts, based on views expressed by some employers, as to whether technologists from the universities will meet the needs of industry as well as those who have qualified by part-time study while working in industry. Again, attention is directed to the desirability of clarifying the confusion which often exists in the public mind between technologists, on one hand, and technicians and members of the engineering craft unions on the other. It welcomes the Committee's recommendation, which is understood to have been implemented, to set up a working group to co-ordinate efforts of Government Departments in a strong and continuing public relations drive favourable to technology.

These various facets of the manpower situation all demonstrate the unsoundness of a rigid demarcation between technology and science, though they do not necessarily invalidate the recent reorganization, provided that really effective means of interdepartmental co-ordination are established. This is equally true of a further related problem to which the Advisory Council directs fresh attention and which is discussed at some length in a section of the report—that of scientific documentation, or ensuring the effective dissemination of the results of scientific and technical effort over as wide a field as possible. Here, the establishment of the new National Lending Library for Science and Technology, largely as the outcome of the work and recommendation of the Advisory Council's Scientific Library and Technical Information Committee, is seen as the chief result of the Council's effort in this field. Its essential counterpart, however, is a National Reference Library of Science and Invention, and the Council's final report includes a timely reminder that this vital project, in spite of some progress, is still uncompleted.

The present report does not enlarge on that situation, and the urgency of the matter could well have been stressed. Nor is this the only feature of the whole field that is far from satisfactory. In consequence of a special review undertaken by the Department of Scientific and Industrial Research at the request of the Minister for Science, the Advisory Council decided to obtain the views of a representative sample of scientists in a survey designed to show what kind of information working scientists find most useful and how they obtain it. This survey, limited in the first instance to chemists and physicists, was undertaken, under the general guidance of Prof. B. H. Flowers, by the Department of Scientific and Industrial Research, with the help of the Chemical Society, the Royal Institute of Chemistry, the Institute of Physics and the Physical Society.

The results of this survey, which identified, if only qualitatively, more or less general views which should facilitate action and the formulation of policy, are summarized in an appendix to the report. While minor differences appear between the methods of chemists and physicists in recording and seeking information, the proposals for improving the available services and the use made of them which emerge from the report are far more interesting and important. Published papers are still regarded as a most useful source of information, but a strong desire for changes and improvements is manifest. More published reviews of all types are needed but with a greater emphasis on those of the introductory, rather than the intermediate or advanced, type. There appears to be no present need for abstract periodicals to increase their coverage, but further investigation of the relative

functions of abstracts and titles seems desirable, and a need was evident for comprehensive abstracts periodicals covering particular disciplines. Some scientists obviously lacked expertise in the use of guides to the literature, and at some stage in their education scientists should be given formal training in the use of scientific literature. Similarly, the Advisory Council stresses that, if university libraries are to be used to the full, more university librarians must be employed with a scientific training and with a broad understanding of the needs of the scientists consulting them.

If such dynamic service is to be achieved, however, there are corollaries which are not examined in the survey or by the Advisory Council itself. Scientists will not be attracted to such a career unless reasonable prospects are provided. This rarely obtains at present, and even less in some of the other types of library which form an essential element in any adequate national library and information system. It is to be hoped that this will be adequately emphasized when, in due course, the Committee on Libraries of the University Grants Committee reports. Meanwhile, the position and the need have been ably analysed by Mr. J. Thompson in an article, "University Libraries and Higher Education", contributed to the *Library Association Record* for November 1964. They could well, however, also receive attention from the new organization for scientific and technical information recommended by a working party set up by the Department of Scientific and Industrial Research at the invitation of the Advisory Council.

This Working Party arose out of proposals made to the Advisory Council by the Council for Scientific and Industrial Research. The Working Party was set up to consider and amplify these proposals and suggested that the new organization would be most effective, at least initially, if it were supported directly by a Government department. It recommended accordingly that all Government scientific and technical information work of a general character should be brought under a single administrative unit in the Ministry of Education and Science, and guided by an independent committee appointed by the Secretary of State. The main functions of this new organization are envisaged as including provision of advice and support in the field of scientific and technical information over the whole range of the natural sciences, their relevant technologies and related aspects of the social sciences, including advice on the participation of the United Kingdom in the work of international agencies in this field. Included also would be the promotion of research and development in scientific communications, classification, storage, retrieval and translation of information, and operation of information services for scientists, technologists and others. While it will also be responsible for existing services, such as the National Lending Library for Science and Technology and grant-aid to the Association of Special Libraries and Information Bureaux (Aslib), as well as for co-ordinating existing and future activities in this field, there has been no reference to the National Central Library or the National Reference Library of Science and Invention, nor to the place of the university libraries, those of the colleges of technology or the contribution of the regional libraries and other public libraries.

All of these are now within the responsibility of the same Minister, and will have an essential part to play if the expenditure of the new organization is to be effective and efficient, whether of the anticipated order of £1.5

million or higher. The Advisory Council is satisfied that there is a need for a new organization on the lines recommended, and stresses again the need for the closest liaison between the new organization and the National Reference Library for Science and Invention. The implications are not discussed, and, however welcome is the emphasis laid in this report on this question of a national policy and organization in library and information work, it does not remove the misgivings which have been aroused by the neglect of such problems in the reorganization of civil science generally.

The Advisory Council notes in passing that it has been required to give some attention to scientific aid to emergent countries in the Commonwealth, particularly in Africa and to Britain's overseas scientific relations in general. It records without comment the demise of the Overseas Research Council, but it points out that Britain's participation in international scientific adventures is bound to grow in importance: the particular topic of high-energy physics and the national programme of scientific research is discussed in a separate section of the report, in which the Council accepts the proposals of the Council of the European Organization for Nuclear Research to develop a new machine of the order of 300 GeV and storage rings to increase the potentialities of the existing 28-GeV machine as scientifically desirable. It recommends that these proposals for developing high-energy physics in the United Kingdom should be supported by the Government, provided the requirements of other fields of science on the scale indicated are also satisfied.

That impinges on the main and most enduring issue which has exercised the Council during its seventeen years of existence; the adequacy of any new arrangements must largely be judged by the competence with which it deals with this question of the scale and balance of Britain's national effort in civil science. Expenditure in this field is estimated at more than ten times the resources available when the Advisory Council was constituted, and demands of which the Advisory Council is already aware could double the present figure in the next five years. The Advisory Council believes that this level of expenditure may be necessary if we are to continue to compete successfully in those fields of science in which we are now operating, and that such a scale would enable the present output of scientists to deploy their abilities fully and to build the essential background to our technological effort in industry as well as provide the trained manpower which industry requires to meet the increasing strength of overseas competition.

Nevertheless, the choice of priorities remains, and the Advisory Council, in reminding us that some choice between expensive fields, such as space technology and high-energy physics, is inevitable, admits that it has never had the powers to deal with this problem. There is also a shrewd reminder of the difficulty of foresight. The Advisory Council itself is of the opinion that Britain is devoting too little of her gross national product to the advancement and exploitation of science, though, like Mr. C. F. Carter and Prof. B. R. Williams in their paper, "Government Scientific Policy and the Growth of the British Economy" (*The Manchester School*; September 1964), it recognizes the difficulties and complexities involved in any such decision.

That, as Mr. Carter and Prof. Williams also recognize, is related to the question of innovation in industry, and to that subject the Advisory Council devotes the longest

section of its report. The Advisory Council has sought to discover whether, in the light of scientific knowledge now available, large-scale investment in an expanded programme of power generation in the electrical industry would be desirable, using funds comparable in size to those required for the development of research in nuclear physics. The recent debate in the House of Lords on the electricity, gas and nuclear energy industries indicated that considerable scope exists for further enquiry in this field, and the discussions which the Advisory Council had with the Ministry of Power and the Central Electricity Generating Board immediately raised points of much wider interest in relation to technological innovation generally.

It is in this wider context that the Advisory Council submitted its conclusions last August to the Secretary of State for Education and Science. Its report points out that, since innovation is the result of applying existing knowledge to the satisfaction of human needs, an increase in innovation is likely to follow a powerful and sustained research effort in any field of knowledge, though the relation is not simple. Technical innovation, however, springs from the combination of an inventive human kind, or an organization willing to venture to risk capital on it, and accordingly, except where there are other motives than financial or economic gain, the enterprise must have good prospect of showing a substantial commercial profit. The circumstances which promote or impede innovation in industries science based or technologically advanced differ from those which affect innovation in traditional industries, or in modern industries which produce consumer goods on a massive scale. While the discussion of this subject differs considerably from that of Prof. I. D. Rattee in his lecture on "Discovery and Invention" (*Nature*, 204, 1017; 1964), in that the Advisory Council is much less ruthless towards the inefficient and backward, the conclusions are broadly similar.

The Advisory Council concluded that very advanced research and development of long-term national importance is required in an increasing number of fields, but this is beyond the capacity of many industries as now organized in Britain, and it instances the generation of electricity. Here it suggests that the possibility of operating through consortia should be studied, with the Government participating as a partner in the enterprise. In the traditional industries, it considers that the position is unlikely to improve without more research or much more attention to the utilization of available knowledge. It would encourage 'innovation' by development contracts, and the Council is confident that here, and in those industries engaged in mass production of consumer goods, research associations should find great scope.

The closer integration of traditional industries with the sciences on which they rest depends above all on the wider employment of scientists and technologists in these industries, and to that end the Advisory Council suggests that Britain should aim at closer relations and deeper understanding between those industries and the universities. However ready the universities are to co-operate and to seek to understand the problems of such industries, it is difficult to visualize an adequate response from the industrial side before such permeation with scientific staff occurs on a sufficient scale: extension of the policy of part-time professors and lecturers from industries presupposes the existence of experienced scientific staff in industry. This is more likely to be a long-term than a short-term result of a wider public understanding

of the importance and status of technology, the promotion of which has already been discussed.

In any consideration of innovation in industry, however, problems of organization loom large, and the Advisory Council stresses the prime importance of management. In this connexion it is pointed out that this is a matter not merely of having scientists or technologists in the highest administrative posts, but equally of dispersing people with scientific and technological qualifications throughout the industrial organization. Such a state of affairs could enable minor technical problems to be solved quickly and major technical ones recognized and referred to the research department for handling by those qualified to do so. This again is part of the unsolved problem of stimulating research and development in the small or backward firm, and to that end this investigation by the Advisory Council does not contribute anything new. It suggests, however, that immediate attention be directed to a thorough study of the means of communication between the innovator and those responsible for determining policy. It also urges the need for examination of the social factors affecting innovation, such as case studies of the social consequences of a major innovation in one of Britain's mature industries.

In this its last report the Advisory Council on Scientific Policy has left its successor—or successors—with some definite lines of enquiry which should be continued or initiated. The report should remove any false ideas that rapid solutions are likely to result from any changes in organization alone: success is more likely to flow from persistent effort in many fields, above all, from effort unhampered by preconceived ideas of any kind. There may well be some concern as to whether the present changes, for a time at least, will impede progress and cause some overlapping or dispersion of effort. This would appear distinctly possible in the arrangements regarding manpower and the responsibility for technology, as well as for information services and libraries. Whatever the future may hold, the Advisory Council on Scientific Policy is manifestly entitled to the nation's gratitude for seventeen years of outstanding service to the nation and to science. Its record is unlikely to be surpassed, and may not be attained, unless its successors are accorded an authority and resources which the Advisory Council itself has never enjoyed.

## VARIATION PRINCIPLES IN COLLISION THEORIES

### Variational Principles in the Theory of Collisions

By Yu. N. Demkov. Translated from the Russian by N. Kemmer. Pp. x + 157. (London and New York: Pergamon Press, 1963.) 42s. net.

VARIATIONAL principles have played an important part in quantum mechanics almost from the very beginning. However, the first applications were confined to the discussion and approximate determination of the energies of bound states of nuclear, atomic and molecular systems. It was not until the 1940's that ways were found for applying variational principles to scattering problems. Since then a variational outlook on the treatment of collision phenomena has been developed which has not only provided new methods for approximate calculation of collision cross-sections but has also led to deeper and clearer theoretical understanding of non-stationary quantum phenomena.

Demkov has presented a very clear account of the way in which variational principles have been derived in collision theory. The first chapter discusses the formulation of the variational principles of Hulthén and of Kohn for both elastic and inelastic collisions. In the next chapter the connexions between these and other variational principles and also perturbation methods are discussed. Applications to the elastic collisions of electrons with hydrogen atoms are given in this chapter to illustrate the use of the principles for actual evaluation of approximate cross-sections. Chapter 3 deals with more formal questions of the symmetry properties of the functionals, the principles of detailed balance and the unitarity of the scattering operator, in terms of variational principles. Finally, in Chapter 4, variational methods are used to obtain results analogous to the virial theorem in classical mechanics.

The author's presentation is very clear and free from unnecessary formalism, while the translation is excellent. It is most instructive reading for any student of quantum mechanics and should certainly be examined carefully by anyone working on atomic collision problems. The only cause for regret is that the price of the book is so high.

HARRIE MASSEY

## ELECTRONIC SPECTRA AND ORGANIC COMPOUNDS

### Interpretation of the Ultraviolet Spectra of Natural Products

By Prof. A. I. Scott. (International Series of Monographs on Organic Chemistry, Vol. 7.) Pp. x + 443. (London and New York: Pergamon Press, 1964.) 84s. net.

INCREASING use of infra-red, nuclear magnetic resonance and mass spectra for the elucidation of the structures of organic compounds may have given the impression that the earlier-developed method of electronic spectra was no longer being used. Prof. Scott's book is a reminder that ultra-violet and visible spectra continue to play a valuable part among the tools of the organic chemist, especially the chemist concerned with natural products. The simultaneous use of all these techniques is advocated to reduce experimentation to a minimum, particularly where only minute amounts of labile material or compounds that are difficult to separate are being handled.

More information will be found in *Interpretation of the Ultraviolet Spectra of Natural Products* than is suggested by its title, because the first part deals systematically with simple chromophores, albeit from an empirical and phenomenological point of view. After an introduction there are chapters on single chromophores, conjugated chromophores, C-aromatic compounds, O-, S-, and N-hetero-aromatic compounds, each of which is liberally illustrated by examples. There is a short chapter by Dr. C. J. W. Brooks on miscellaneous applications with particular mention of analytical estimations and colour reactions. This leads on to the longest chapter, 85 pages, on the investigation of molecular structure, in which selected classes of natural products are discussed in greater detail. The final chapter takes a range of specific examples of natural products of quite complicated structures, including terramycin, shellolic acid, some alkaloids, mould metabolites, streptimidone, limonin and plumieride, and shows how the electronic spectra together with other spectroscopic and chemical evidence have allowed the structures to be elucidated. The book concludes with an appendix on steroids consisting mainly of 54 pages of tabulated spectra.

Some of the less desirable features of the book deserve comment. The index is inadequate, having only approximately 1,000 entries for 443 pages. Many readers will seek

spectroscopic information on specific compounds and not find an entry even though the compound may be discussed in the text. While there are copious references to the original literature, it is noteworthy that fewer than 9 per cent of the citations refer to the post-1959 period, and almost the entire number of these to 1960 and 1961. There are a number of blemishes in the production, carelessly printed formulae and minor typographical errors, which are more irritating than confusing. In some sections the author's arguments would have been more clear if he had been more concise and if the tables had been more compact and placed closer to the relevant discussion. Some of the structures are accompanied by wave-lengths but not by intensities, which have to be sought for in the text or in the tables. In some cases intensities are not quoted at all, for example, for three of the four bands of acridine, and for riboflavin. A more serious comment is that some of the numerical values quoted do not agree well with values that are given in the literature.

Prof. Scott is to be congratulated on having gathered together so much information and imposed an order on it. Undoubtedly all natural product chemists and many others as well will want to have ready access to this book.

C. J. TIMMONS

## A COURSE IN ENDOCRINOLOGY

### Experimental Endocrinology

A Sourcebook of Basic Techniques. By M. X. Zarrow, J. M. Yochim and J. L. McCarthy. With a chapter on Invertebrate Hormones by R. C. Sanborn. Pp. xvi + 519. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 107s. 6d.

IN the curriculum of some North American universities endocrinology receives special consideration, but in Britain it is taught largely in the context of other main subjects such as zoology, physiology and medicine, and formal instruction for the advanced student is uncommon. A course in endocrinology that was first taught in the laboratory of Prof. F. L. Hisaw in 1946 forms the basis of a new book, *Experimental Endocrinology. A Sourcebook of Basic Techniques*. The scope of this book is clearly stated in the preface by Prof. Zarrow: to provide material for "an advanced course or for use by the individual student in a project course". More than a hundred experiments are described, ranging from the classical methods of the 1930's to those developed more recently (up to about 1962), emphasizing the widespread derivation of techniques from disciplines that include anatomy and physiology, biochemistry and pharmacology. It is both text-book and laboratory manual, and the authors claim that about 85 per cent of the experiments they describe have worked successfully "at the student level".

An earlier definition of a hormone as "a specific chemical entity that is secreted into the blood by a well-defined group of cells and is transported via the vascular system to a site distant from its point of origin, where its action takes place", is considered to be no longer adequate. It is now expressed in more flexible terms to include those "physiological organic substances" secreted from a "relatively restricted area of the organism" that diffuse or are transported to sites of action where their effect is one of adjustment or integration. Although this raises problems with respect to certain substances, it goes some way to describe others such as the posterior pituitary hormones vasopressin and oxytocin.

Classified according to their chemical structure, the hormones are divided into three main groups: first, steroids related to cholesterol, such as oestrogens and adrenocorticoids; secondly, amino-acids or their deriva-

tives, including catechol amines and the thyroid hormones; and thirdly, polypeptides and proteins such as relaxin and insulin, corticotrophin and parathormone. The main members of these groups are considered in thirteen chapters in which about one-half of the text is devoted to the source and nature of the hormone, its biological effects and mode of action, and its biosynthesis and metabolism. This is followed by a separate section dealing with the basis of suitable assays, biological and chemical. In chapters on oestrogens, androgens, thyroid hormones, and, to a lesser extent, gonadotrophins, the question of anti-hormones is considered. The text covers numerous aspects: physical properties of somatotrophin and parathormone, amino-acid sequences of polypeptide and protein hormones, the secretion of catechol amines, the action of pancreatic hormones in metabolic pathways, the interrelationships of gonadotrophins in the female mammal, and many others. In the final chapter on invertebrate hormones, R. C. Sanborn discusses the regulation of moulting, growth and reproduction in the Insecta and the Crustacea as well as activity rhythms and pheromones, to give a few examples.

Important contributions have been made by experiments that involve ablation of endocrine glands, replacement therapy and the isolation and estimation of hormones. In the second half of every chapter the authors illustrate the use of these techniques in experimental endocrinology. There is a valuable series of experiments that includes ablation of glands, described with usually helpful diagrams (hypophysectomy in rat and chicken, parathyroidectomy in pigeon, adrenalectomy in rat), techniques of transplantation and parabiosis, biological assays and experiments using replacement therapy, and chemical procedures for the extraction and estimation of hormones involving chromatography, fluorimetry, spectrophotometry and radioisotope methods. The series is not exhaustive, and inconsistencies occur—for example, the absence of a chemical determination for progesterone when more complex methods are introduced in other sections—but many laboratories will find here much useful information if it is understood that the book is intended primarily for course-work and not as a definitive account of experiments in endocrinology.

The text is usually concise, comprehensive and well-documented, the authors presenting much of their material in tabular form which, although readily assimilable, tends to repeat information already given in the text. Similarly, there is a repetition of biosynthetic pathways in some chapters on steroids that could have been avoided by a composite and more informative diagram as used to describe the metabolism of adrenocorticoids. Several inconsistencies were noted, especially in the presentation of references to original sources, and for a book of this price, in which the print and lay-out are generally good, it is to be regretted that the illustrations frequently lack clarity and contrast.

It is hoped that the authors will be stimulated to produce future editions of this book as further techniques, suitable for teaching courses, become available.

R. B. HEAP

## REVIEW OF CATALYSIS

### Advances in Catalysis and Related Subjects

Vol. 14. Edited by D. D. Eley, Herman Pines and Paul B. Weisz. Pp. xii + 522. (New York and London: Academic Press, 1963.) 114s. 6d.

VOLUME 14 of *Advances in Catalysis and Related Subjects* presents again the now familiar but still admirable annual medley of review articles on adsorption and catalysis, together with a welcome intrusion from a cognate region of biochemistry.

In two very helpful accounts of techniques, it is gratifying to find proper credit given to early workers: much recent writing seems to imply that the present-day solutions emerged fully-fledged within the past decade. Leftin and Hobson in "Application of Spectrophotometry to the Study of Catalyst Systems" (83 pp. and references 4 pp.) deal with optical absorption spectroscopy, applied to the investigation of some chemisorbed complexes on metals, oxides and salts; coverage is complete but acid catalysts, especially silica-aluminas, receive most attention as befits the interests of these authors and the pattern of previous reviews. Erlich's "Modern Methods in Surface Kinetics" (168 pp. and references 4 pp.) provides, in characteristic style, a thorough survey of flash desorption, field emission microscopy and ultrahigh vacuum technique (both methods and typical results) with a timely section on practical details. Evidently these powerful tools, together with low-energy electron-diffraction, will soon be commonplace in research on clean metal surfaces. But when will the bridge between surface physics and surface chemistry be consolidated?

There are three contributions to the mainstream of catalysis, each in different vein. Mars, Scholten and Zwietering, in "The Catalytic Decomposition of Formic Acid" (75 pp. and references 4 pp.), survey present research and points of view concerning this model-reaction, about which discussion has sometimes reached polemic-force; dehydrogenation and dehydration over metals and oxides are discussed in detail and related to the water-gas shift reaction and the decomposition of bulk formates. The system is well suited to tests of the intermediate compound theory of catalysis, but the authors are rightly guarded in their appraisal of recent generalizations. Catalysis in preparative organic chemistry is represented by the valuable, descriptive paper entitled "Hydrogenation of Pyridines and Quinolines" (45 pp. and references 5 pp.) by Freifelder, which collects results obtained on the selective hydrogenation of these awkward, self-poisoning heterocycles: one feels here the lack of a short section on mechanism designed to crystallize the topic. Margolis covers a wide and important field somewhat discursively in the chapter entitled "Catalytic Oxidation of Hydrocarbons" (68 pp. and references 5 pp.). The trend of Russian research emerges strongly, but strange phraseology obscures some passages, and vital points, such as the evidence for various forms of chemisorbed oxygen, are treated too lightly. There is a nice counterpoint between electron-transfer and chemical complex theories, but one is left wondering whether sensitive surface-potential methods are central to the investigation of polyfunctional surfaces.

Calvin approaches the fundamental biochemical photocatalytic problem, in "Quantum Conversion in Chemoplasts" (31 pp. and references 3 pp.), with the aid of photoconductive organic systems suggested by present organic semiconductor research, and draws some interesting parallels: it is exciting to see how the gap between the quick and the dead narrows.

In all, a well-composed medley—but surely the editor cannot still maintain that such diverse catalytic chemistry comprises a discipline "in its own right".

D. A. DOWDEN

## POPULAR PRESENTATION OF MEDICAL RESEARCH

### Our Most Interesting Diseases

By Harold Burn. Pp. 180. (London: George Allen and Unwin Ltd., 1964.) 25s.

TO give to the lay public a description of the growing points of medical research to-day is an important and urgent task. The difficulty that the writer has to overcome

is one of communication: it is essential to exercise economy in the use of technical terms and to explain adequately and in simple language those that are used. Once again Prof. H. Burn has set himself this task and once again he has been successful. This book deserves to find many readers.

The topics that Prof. Burn has selected are all of great importance to those who live in a modern society. It is interesting that in his catalogue of our most interesting diseases the microbial infections are not listed. That they are omitted is a development that we owe to relatively recent successes in chemotherapy. The diseases that this book deals with are mainly those of late or middle age. Cancer, vascular and heart disease, gastric and duodenal ulcer, bronchitis—these are topics that we find discussed.

In a book of this kind the reader cannot expect to find final or authoritative answers. The description of modern research is a tale of trial and error. The author's individual attitude must determine also how he selects and weighs the material discussed. What matters is that what is selected is adequately described, and that in each chapter the story has cohesion and adds up to give a clear picture of the present state of our knowledge. There are a number of instances where the reader would like to know if all the experts are in agreement with Prof. Burn's evaluation of the evidence; but it is one of the great merits of this book that we are given the evidence and that we are allowed to arrive at our own conclusions.

Prof. Burn does not see medical science as a body of knowledge that is unrelated to our lives. The influence of environment, of social conditions and habits on disease and health is discussed. Almost inevitably this leads in the final chapter of the book to a guide for healthier living. We are told to eat less, to drink less and to smoke less and not to give up physical exercise. These precepts are given with moderation and common sense; and this gives the author's injunctions both authority and authenticity.

H. BLASCHKO

## THEORY AND PRACTICE OF BIOLOGICAL CONTROL

### Biological Control of Insect Pests and Weeds

Edited by Paul DeBach. Pp. xxiv + 844. (London: Chapman and Hall, Ltd., 1964.) 120s.

C. P. CLAUSEN once remarked that insects are their own worst enemies. Their other enemies include pathogenic micro-organisms, while their other victims include plants. These ideas are well illustrated by numerous successes in the biological control of pests and weeds described in this book. Many of the successes have been in California. This is attributable partly to local ecological features, but also in great measure to a number of enthusiastic exponents of the method, notably to the leadership of the late Prof. Harry S. Smith, to whom the book is dedicated. Its 16 authors are all present or past staff members of the University of California, all specialists on the topics with which they deal, some of them pre-eminent authorities. The outcome is a most impressive and comprehensive treatise, in which the advantages of multiple authorship have been fully exploited; thanks to careful planning and editing, the disadvantages have, on the whole, been overcome. The subject is clearly and logically subdivided in a scheme fully set out in a contents list of 15 pages.

In the first of the eight sections, P. DeBach deals with the scope of biological control and R. L. Doutt with its historical development. In Section 2, the first 72 pages are devoted to an outline of the development of population ecology, and to a discussion of ideas of natural control

and the role of density-dependent processes, by C. B. Huffaker and P. S. Messenger. Then Doutt and DeBach discuss some much debated questions dealing with biological control—on population equilibria; the effects of attacks by more than one parasite in individual hosts, and on parasites by hyperparasites; the relative value of parasites and predators; the sequence theory; the island theory; the influence of different types of environment on the chances of success, and so on. They have skilfully fitted into 24 pages the essential facts and views, and their own conclusions, apparently without serious omissions. In Section 3, Doutt and K. S. Hagen deal with the biology of natural enemies (100 pages), and E. I. Schlinger and Doutt discuss systematics in relation to biological control, beginning with theory and concluding with keys to families of entomophagous insects.

The fourth section of 144 pages is in effect a detailed practical handbook by six of the authors on the methods of collection, maintenance, release and recovery of entomophagous insects, illustrated with photographs of insectaries and equipment.

In the fifth section, of 83 pages, five authors describe methods of enhancing the effectiveness of parasites and predators by such measures as the introduction of supplementary hosts or food and the modification of the environment, and discuss the integration of chemical and biological control. In Section 6 (113 pages), E. A. Steinhaus deals with microbial diseases of insects, Y. Tanada with their epizootiology, and M. E. Martignoni and I. M. Hall with their mass production and use in control. In Section 7, of 40 pages, Huffaker outlines the fundamentals of the biological control of weeds, and J. K. Holloway describes the success in various countries of measures to control 13 major weeds by the introduction of insects. In a concluding section of similar length, DeBach lists over 200 cases of biological control (of insect pests) rated as completely, substantially or as partly successful, and discusses present trends and future possibilities.

There is a bibliography of more than 2,500 titles, extending to mid-1961, and an index to species. The book is compact and well produced; the numerous illustrations are on the whole effective, although a few of the half-tone pictures are too small and some of the line drawings are poorly reproduced.

Hitherto the standard work in English has been H. L. Sweetman's *The Principles of Biological Control* (revised 1958). The plans of the two books are somewhat similar, but Sweetman's is much shorter (and may still be preferred as a text for students). *Biological Control of Insects and Weeds* is more comprehensive, more authoritative and more up to date, and presents the subject more adequately in its theoretical setting. It will no doubt be the definitive work for many years to come.

## SCIENTIFIC AND PHILOSOPHICAL UNCERTAINTY

### Scientific Uncertainty, and Information

By Prof. Leon Brillouin. Pp. xiv+164. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 52s.

OUR knowledge of the world is inevitably imprecise and uncertain. In his latest book, Prof. Brillouin stresses, illustrates, and draws rather far-reaching consequences from this fact. His stress on the importance and inevitableness of imprecision is very welcome. Experimental error has too often been discounted as a tiresome but trivial excrescence on the neat deductive structure of science. This has led, on one hand, to needless alarm at the appearance of theories incorporating imprecision and, on the other, to misguided attacks on the

notion that scientific explanation is deductive. The second part of the book, "Uncertainty in Classical Mechanics", should help to dispel the former complaint. There is a valuable discussion and extension of Poincaré's theorem. Several examples are given of instability, and especially of discontinuities of prediction arising from infinitesimal changes in initial conditions. In all this the author gives due credit to Poincaré; he might have acknowledged his debt to Duhem's *The Aim and Structure of Physical Theory*, which also discusses the "mathematics of approximation" in some detail.

The first part, "Information and Uncertainty in Science", which strays into philosophy, is not nearly so good. Here Duhem not merely forestalls (by nearly fifty years) but also far exceeds. It is a great pity that eminent scientists will not inform themselves about philosophy before pronouncing on it (and, of course, vice versa). The author's scientific insights are offset by a philosophical confusion which greatly diminishes the value of what might have been a major work in the philosophy of science. To start with, positivism is confused with solipsism: "A narrow positivism intended to limit each individual to the knowledge of his own sensations: other human beings around him appeared to him only as ghosts" (p. 47). This is just part of the more serious confusion about the existence of an external world: "The scientist should never confuse the actual outside world with his *self-invented physical world model*" (p. 51) ... "The modern scientist must absolutely renounce the idea of a real objective world" (p. 52). Must the 'modern scientist' become a 'narrow positivist'? If there is no 'actual outside' (= 'real objective'?) world, how does the scientist's confusion arise? On p. 50, Planck is represented as saying: "This world is not directly accessible to us". Three lines below, this is referred to with the remark: "what is the use of speaking of an inaccessible world?"—which is scarcely a faithful reproduction.

A corollary of the author's confusion about reality is his equivocal attitude to fact and theory. In the introduction, the assertion: "We select experimental results that appear to us as logically connected together, and we ignore many facts that do not fit into our 'logic'", is immediately followed by the scarcely compatible assertion: "... a theory may be discarded, while facts remain ... and the connexions (between the facts) will be maintained in a different theory". In what sense do facts 'remain' if we are free (to an extent) to ignore those which the new theory does not explain? This is a serious problem, but oscillating between contradictory answers is no way to deal with it. This uncertainty pervades the whole book: warnings of the temporary, relative, corrigible nature of theories are interspersed with passages in which consequences of quantum and information theories are presented as facts about the world.

One particular consequence is made a great deal too much of, namely the "interaction between observer and the observed element" (p. 52). In the first place, the author seems to suppose that pointing out that "the interaction is finite" refutes what "was currently assumed, that this interaction could be made very small and negligible" (p. 52). In the second place, he confuses this with the impossibility of making precise predictions. But it does not follow that because an observer interacts with what he observes he cannot know the effect of his observation and hence compute both what the future will be and what it would have been if he had not made the observation. Given some present-day theory, it may follow; but I take the author to be making a quite general point.

Of the other topics dealt with, there is space only to record further confusion about causality, determinism and the arrow of time, and an appalling looseness in applying the concepts of information and probability.

D. H. MELLOR

**Animal Ancestors**

By Sonia Cole. Drawings and Reconstructions by M. Maitland Howard. Pp. 78. (London: Phoenix House, Ltd.; New York: E. P. Dutton and Co., Inc., 1964.) 13s. 6d. net.

WHEN some striking palaeontological find is made, the non-specialist student has until now had great difficulty in finding any information other than in works of a very technical and scholarly nature, or in the often rather inaccurate and very generalized popular science books. Mrs. Cole is to be congratulated in her production of a clear, concise and thoroughly readable work which fills this gap and makes mammalian palaeontology a living science which can be compared with our own personal knowledge of the world we live in to-day. Miss Maitland Howard's excellent drawings are an essential part of this book; the differentiation, by colour, of known fact from enlightened supposition is particularly clear.

Mammalian evolution is a very wide subject and extremely difficult to condense into a book which is easily read, light to handle and reasonable in price; it is inevitable that much has to be left out. No two palaeontologists would agree on the choice of priorities, or even on the much debated branches of family trees, which in *Animal Ancestors* have to be very generalized and so unfortunately lose some of their value. The relationship between hyraxes and elephants is perhaps too strongly emphasized; the mention of undescribed remains from the Upper Miocene of Kenya which could be a connecting link between anthracotheres and hippos as having "actually been proved" seems rather premature.

There is a full and comprehensive index, so often omitted in works of this nature; the addition of a list of books for further reading would be of benefit to those readers wishing to continue studying the subject which Mrs. Cole and Miss Maitland Howard have introduced with such clarity. I feel sure *Animal Ancestors* will have a wide appeal and will quickly find its way on to the shelves of public libraries and educational institutions as well as private collections.

S. C. CORYNDON

**Monograph on Radio Waves and Circuits**

Proceedings of Commission VI on Radio Waves and Circuits during the XIIIth General Assembly of URSI, London, September 1960. Edited by Samuel Silver. Pp. vii + 377. (Amsterdam, London and New York: Elsevier Publishing Company, 1963.) 150s.

THIS book is primarily a collection of papers describing new work, prepared by acknowledged experts for discussion at meetings of specialists in Commission VI of the International Scientific Radio Union. Even in one small volume the range of subjects touched on is wide: electromagnetic wave boundary problems, propagation of waves in statistically inhomogeneous media, information theory and coding problems, aeriels and data-processing for radio astronomy, and solid-state circuits. The diversity of subjects covered by Commission VI is explained by the editor in terms of the realization of the need for a co-ordinating unit within the International Scientific Radio Union which could deal with the many expanding new areas of research and the new developments in applied mathematics; it would bring together engineers, physicists and mathematicians on problems which were previously regarded as purely ancillary by the other Commissions, the interests of which were turning more to the geophysical and cosmological import of radio propagation research. Commission VI was formed with this object in mind.

Most of the papers in the book describe original work on a particular aspect of a subject, although one or two are in the nature of reviews, and useful references are given. As with all material in the forefront of knowledge, the papers provoked discussion at the meetings,

and this discussion is reported in the book; some is of philosophical interest, as, for example, that on surface waves.

It should be emphasized again that this publication is primarily a collection of the papers which were presented at Commission VI, and does not purport to be a text-book. It will be of interest to specialists and those wishing to sense developments taking place in new fields. At the price of £7 10s. this is not, perhaps, a book which the average reader would expect to buy, but he might, nevertheless, expect to find it on the shelves of a good specialist library.

R. W. MEADOWS

**Tables of Natural and Common Logarithms to 110 Decimals**

By W. E. Mansell. (Royal Society Mathematical Tables, Vol. 8.) Pp. xviii + 95. (Cambridge: At the University Press, 1964. Published for the Royal Society.) 40s. net.

THESE tables originated in a part of the extensive computations made, without machine, by William Ernest Mansell (1877-1953), an accountant, who in his will made provision for their publication. They have been edited by Dr. A. J. Thompson, with assistance in checking from several persons and institutions. They give both logarithms to base  $e$  (pp. 1-47) and logarithms to base 10 (pp. 49-95), to 110 decimals, of all integers up to 1,000 and also of  $1+m.10^{-n}$ , where  $m=1(1)9$ ,  $n=5(1)12$ . An introduction explaining construction, checking and use of the tables ends (p. xviii) with a noteworthy table of mathematical constants to 110 decimals.

There is no difficulty in justifying a certain amount of tabulation of important functions to, say, 20 or 25 decimals. Dr. Thompson's own monumental 20-decimal *Logarithmetica Britannica* must have struck many numerical analysts as particularly well judged. To justify tabulation to more than 100 decimals is always more difficult. The editor acknowledges that logarithms to so many decimals are infrequently required. One feels that Mansell must have been a compulsive calculator who followed, with no more equipment and with similar *éclat*, in the footsteps of those great computers Abraham Sharp (1653-1742) and Isaac Wolfram (c. 1725-c. 1787). It is impossible not to admire a work so definitive of its kind, and it is pleasant to think that these logarithms, known for some time to have been computed, have now been fortunate in finding skilful editing and publication. Any computing enthusiast who purchases this volume will acquire, in a moderate compass, a powerful tool to which he will probably turn more often than he at first anticipates. It goes without saying that the volume should be available in specialized libraries of numerical analysis.

ALAN FLETCHER

**Chymia**

Annual Studies in the History of Chemistry, Vol. 9. Editor-in-Chief: Henry M. Leicester. Pp. 221. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1964.) 40s. net.

VOLUME 9 of *Chymia* contains more articles than usual and covers a range of topics. There are obituaries, with portraits of Eva V. Armstrong and Clara de Milt, both contributors to the history of chemistry. There are three papers dealing with, or connected with, Sir Humphry Davy, one of these concerning the work of Grotthuss on gaseous combustion. Three papers on chemistry and technology in the East, and discussions of chemical laboratories in Russia, indicators, Sir B. C. Brodie and his calculus of chemical operations, elements and nucleosynthesis in the nineteenth century, Boyle on the degradation of gold, mining education in South America, and the water controversy, make up the rest of this interesting collection.

J. R. PARTINGTON

## RADIO PULSES FROM EXTENSIVE COSMIC-RAY AIR SHOWERS

By DR. J. V. JELLEY and J. H. FRUIN  
Atomic Energy Research Establishment, Harwell

PROF. N. A. PORTER and T. C. WEEKES  
University College, Dublin

AND

PROF. F. G. SMITH and R. A. PORTER  
University of Manchester, Nuffield Radio Astronomy Laboratories, Jodrell Bank

VARIOUS proposals have been considered for the detection of large cosmic-ray air showers by radio techniques. Neither the original proposal of pulse radar<sup>1</sup> nor the passive detection of Čerenkov radiation at microwave frequencies<sup>2</sup> now appears to be feasible. A re-assessment of the possibilities of Čerenkov radiation at longer wave-lengths has, however, been stimulated by the recent suggestion<sup>3</sup> that a considerable enhancement of the intensity may be expected in the radiation from an electron-photon cascade. This is due to a fractional negative charge excess  $\varepsilon$  arising from the annihilation of positrons in flight. For a shower with a total of  $N$  particles, the radiation intensity at low frequencies is proportional to  $(\varepsilon N)^2 \nu \delta\nu$  within a bandwidth  $\delta\nu$  at a frequency  $\nu$ , and the enhancement factor is  $\varepsilon^2 N$  over that from  $N$  particles radiating incoherently. In a typical shower of primary energy  $E_0 \sim 10^{15}$  eV, for which  $N \sim 10^8$  and the electron and positron energies are of order  $10^8$  eV, we expect  $\varepsilon \sim 0.1$ , and  $\varepsilon^2 N \sim 10^4$ .

If we consider a shower front as a disk of thickness  $t$  and area  $S$  incident vertically close to an aerial array of area  $A$ , two conditions must be satisfied to achieve the maximum mutual coherence: (i) the wave-length  $\lambda$  must exceed  $t$ , and (ii) the radiation from all parts of the shower front must arrive in the same relative phase at all elements of  $A$ . In such a shower  $t \sim 2$  m (ref. 4) and the effective radius of the shower is  $\sim 50$  m (ref. 5), so that these conditions are reasonably satisfied for  $\lambda \geq 4$  m and for altitudes  $\geq 3$  km.

The present experiment was conducted on the basis of favourable estimates of the expected yield from this enhanced Čerenkov radiation. Cosmic-ray showers in the energy region  $10^{15}$ – $10^{16}$  eV were detected at a rate of  $\sim 3.2$  h<sup>-1</sup> with a simple array of three Geiger-Müller counter trays  $G$  (Fig. 1) operated in coincidence (resolving time 5  $\mu$ sec). These detectors also included smaller counters which operated a hodoscope; the display on this instrument gave some indication of the total energy and position of the shower. To eliminate spurious events, the entire shower recording system, including the Geiger counters, was battery operated. The 20- $\mu$ sec time-bases of a double-beam recording oscillograph were triggered by shower coincidences. As a control the oscillograph was triggered artificially every half-hour.

The choice of wave-length and bandwidth was dictated mainly by available

frequencies locally free from radio and television signals. It was decided to operate at  $\nu = 44$  Mc/s ( $\lambda = 6.8$  m) and  $\delta\nu = 4$  Mc/s. The receiving aerial  $A$  consisted of a wide-band broadside array of 72 full-wave dipoles oriented east-west, and supported  $\sim \lambda/8$  above the ground; these were connected by open-line feeders to a transistorized pre-amplifier  $P$  situated at the centre of the array. The 44-Mc/s signal passed through a delay unit  $\Delta t$  (of delay  $\sim 5$   $\mu$ s) to the receiver, consisting of tuned radio-frequency stages followed by a square-law

Fig. 1. Arrangement of the receiving apparatus. Coincident pulses from the Geiger counters  $G$  trigger an oscillograph which displays the output of the receiver delayed by  $\Delta t$ .  $P$  is a transistor pre-amplifier at the aerial array,  $A$ . The transmitter  $T$  can be triggered by a single counter  $G$ .

Fig. 2. Histograms showing frequency of occurrence of the fluctuation of largest amplitude along the time-base, between 0 and 18  $\mu$ sec. The upper histogram is for 1,117 randomly triggered recordings, and the lower histogram is for 1,794 shower-triggered recordings.

Fig. 3. Histograms showing integrated amplitudes of fluctuations for the same recordings as in Fig. 2

detector, and was then applied to the deflexion circuits of one beam of the oscillograph, the second beam carrying a 4-Mc/s sine-wave for calibration purposes. All the low-level stages of the receiver were run from an independent battery supply, and the total power was monitored on a chart recorder. As required, a small 44-Mc/s pulsed transmitter *T*, connected to a dipole *D*, could be driven from one of the counters. The sensitivity of the receiver was limited by cosmic noise, at a system noise temperature varying between 7,000° K and 14,000° K according to sidereal time.

The following results were obtained. During the recording of 1,799 showers five pulses have been observed which were bandwidth-limited in duration and which had amplitudes of 8, 10, 10, 11 and > 45 (off scale) times the root mean square noise level, corresponding to received energies of 4, 5, 3, 3 and >  $20 \times 10^{-12}$  ergs. These all had delays of between 5.4 and 6.0 μsec with respect to the start of the time-base. No bandwidth-limited pulses were observed in the intervals 0–5 or 6–20 μsec on any of the 1,799 shower recordings, and no such pulses were observed on any portion of the 20-μsec time-bases for the 1,117 artificially triggered recordings.

A statistical analysis of the recordings was made to search for smaller events. Fig. 2 shows histograms both for 1,794 shower-triggered and for 1,117 artificially triggered recordings, in which the ordinates represent

frequency of occurrence of the fluctuation of greatest amplitude along the time-base, between 0 and 18 μsec. Fig. 3 shows a similar histogram in which the ordinates represent the integrated amplitudes of the fluctuations. Excluding the five large pulses mentioned earlier, the main peaks in both histograms occur in the interval 5.5 to 6.0 μsec. In Fig. 3 the peak of the histogram is four times the standard deviation of the fluctuations. The pulses were observed to have a time-delay identical with that from the test transmitter when it was driven from a single counter, after allowing for the delay in firing the counters themselves. This latter delay, which averages 0.75 μsec, and which was determined in a separate experiment, is sufficient to allow us to eliminate completely the possibility that

the observed radio pulses originated in the electronics of the Geiger-Müller counter circuits.

These observations lead us to conclude that short radio pulses of duration < 0.25 μsec have been observed from extensive air showers. Further details of the work will be presented in due course, and experiments are to continue.

While the energy received in these pulses is consistent with the hypothesis of enhanced Čerenkov radiation, it appears also that pulses of comparable amplitude may be expected to arise from the separation of charges in the Earth's magnetic field. This latter radiation would be linearly polarized east-west, affording some possibility of distinguishing between these two mechanisms. We have also considered bremsstrahlung and transition radiation as possible origins of the pulses, but we believe these to be of secondary importance. We also believe that direct effects of induction by the shower particles in close proximity to the aerial elements are negligible.

We thank Sir Bernard Lovell for his enthusiasm and encouragement throughout this work, and also for making available the wide facilities at Jodrell Bank.

## A THEORY OF MACROMOLECULAR AND CELLULAR ORIGINS

By PROF. SIDNEY W. FOX

Institute of Molecular Evolution, University of Miami, Coral Gables, Florida, and Institute for Space Biosciences, Florida State University, Tallahassee, Florida

AT this point in the history of science, descriptions of life can be treated more rigorously and with less controversy than can comprehensive definitions of life. Two outstanding aspects of the description have been its bewildering variety and the overwhelming complexity of its units.

The first quality of variety is that which clearly confronted Charles Darwin, A. R. Wallace, other naturalists, all scientists, and indeed all thinking people more than a century ago. A general dismay engendered in attempting to understand such variety was dispelled by resort to the evolutionary principles which rely on progression from simplicity to complexity.

In this century, we are confronted with the problem which concerns the processes which must have been a prelude to the primitive organism from which all species,

according to Darwin, descended. From present vantage points the complexities of the incompletely understood molecules of protein or nucleic acid can easily be overwhelming, as can the chemical and structural complexity of the simplest cell that we might visualize. The heart of the problem has been aptly stated at one level by Harold Blum<sup>1</sup> as follows:

"... I do not see, for example, how proteins could have leapt suddenly into being. . . .

"The riddle seems to be: *How, when no life existed, did substances come into being which today are absolutely essential to living systems yet which can only be formed by those systems?* [italics Blum's]. It seems begging the question to suggest that the first protein molecules were formed by some more primitive 'non-protein living system', for it still remains to define and account for the origin of that system."

We can, again, hope to learn by honouring, however, in heuristic experiments the evolutionary principles of the stepwise development of complexity from simplicity and of the internal self-limitation of such development<sup>2</sup>. This philosophy is truly naturalistic in that it emulates the empirical approach which the evolutionist is required to impute to the primitive environment.

Although much of the knowledge of biochemical origins has been controversial, fairly general agreement now exists for the analytical outline of the problem of the origin of the first terrestrial organism (Table 1).

Table 1. SUBORDINATE PROBLEMS OF THE ORIGIN OF THE FIRST ORGANISM

- (1) Production and proliferation of organic micromolecules from the simplest compounds.
- (2) Spontaneous generation of macromolecules.
  - (a) Protein.
  - (b) Nucleic acid.
  - (c) Polysaccharide.
- (3) Self-organization of multimolecular systems (precellular forms).
  - (a) Membranous properties.
  - (b) Growth.
  - (c) Division.
- (4) Origin of metabolism.

This analysis is evolutionary in that it, in large measure, proceeds from simplicity to complexity. It also constitutes a gross outline of biochemistry. The sequence in the outline is based on a premise of the emergence of the first complex macromolecules prior to the origin of cells. Perhaps most interesting is the fact that almost entirely within the past decade an experimental model for each item in the outline has been brought forward. The problem is regarded by increasing numbers of theorists as solvable; the more favourable evaluations regard the problem in principle as more solved than unsolved.

The experimental demonstrations of the geological origin of biochemical substances indicate not necessarily what did happen, but what might have happened. The problem may now be viewed more as one that requires limiting of speculation by determining which model reactions examined in the laboratory are sequentially compatible, rather than as a problem of determining at least one way in which each key biochemical substance might have arisen spontaneously. Investigation of the variation in volcanic gases in eruption<sup>3</sup>, for example, helps to emphasize the tremendous variety of possible spontaneous chemical reactions in the history of the Earth.

The intellectual climate and technical understanding which stimulated and permitted the experiments that have been recorded owed much of their basis to the detailed proposals of Oparin<sup>4,5</sup>, Haldane<sup>6</sup>, Bernal<sup>7</sup>, Blum<sup>1</sup>, Calvin<sup>8</sup>, Urey<sup>9</sup>, Wald<sup>10</sup>, and others.

The first experiments expressly designed to explain the origin of organic compounds such as occur in living things were those of Calvin *et al.*<sup>8</sup>, who converted carbon dioxide and water to formaldehyde and formic acid in the cyclotron. A primitive atmosphere having some carbon dioxide is in accord with the models of Rubey<sup>11</sup>, Revelle<sup>12</sup> and Bernal<sup>7</sup>. Through the aldol condensation, one could visualize the formation of carbon-carbon bonds and a variety of organic compounds from formaldehyde. It is Calvin who deserves the credit for initiating the era of experimental chemical abiogenesis. Additional attention to experimental abiogenesis was stimulated by the Urey-Miller experiments, using electrical discharge in a 'primitive atmosphere'<sup>13</sup>. Miller obtained four amino-acids of the protein type and many other organic compounds<sup>14,15</sup>.

As Miller pointed out<sup>15</sup>, Löb<sup>16</sup> had earlier (1913) synthesized glycine by electric discharge in a mixture of carbon monoxide, ammonia and water. Many papers published in the era of early organic chemistry can, in fact, be re-interpreted in the more modern context of biochemical origins. Löb was actually close to such interpretation inasmuch as he proposed his synthesis as a model of reactions that could occur in Nature.

Apart from amino-acids, which could arise in many ways demonstrated in the laboratory<sup>17</sup>, other micro-

molecules which have been synthesized in a presumably geological fashion are the monosaccharides<sup>18,19</sup> (especially deoxyribose<sup>20</sup>), urea<sup>15</sup>, nitrogen bases<sup>21,22</sup> of nucleic acid, and the biochemically significant energy transfer substance, ATP (ref. 23). The production of guanine is noteworthy in that it arises during heating of amino-acids<sup>24</sup>, a process which also leads to salient macromolecules.

In view of the attention which has been devoted to abiotic syntheses of amino-acids, the finding that most of the amino-acids common to protein are produced simultaneously from methane, ammonia and water at 1,000° C, in the volcanic range of temperature, may be especially pertinent<sup>25</sup>.

Although amino-acids have resulted under many sets of conditions, indicating the possibility of their synthesis under primordial conditions, the synthesis from primitive gases has been investigated only recently. Dr. Harada has examined the conversion of ammonia, water and methane at volcanic temperatures to products hydrolysable to amino-acids<sup>25</sup>. He used vapour phase reactions of these gases through beds of silica gel, silica beach sand, a volcanic beach sand from Stromboli, and alumina gel. Except for the two kinds of silica, the results were quite different. Amino-acid formation was not observed at 800°, but it was evident at 900°. In each of many experiments, fourteen of the eighteen common amino-acids were identified. Two of the other four, histidine and tryptophan, will require special identification. Cystine and methionine could not be anticipated inasmuch as no form of sulphur was included in the reaction. This absence is part of the evidence that the amino-acids are not due to hydrolysates of microbial contaminants. No amino-acids of a non-protein variety have been found in such a reaction product. Examinations of this type have been indicated by the continuing development of the thermal theory<sup>26</sup>. At about the same time, the laboratories of Ponnampetuma and of Oró<sup>1</sup> had begun similar investigations<sup>27</sup>.

The interest in explaining the origin of amino-acids, manifest in the fact that so many possibilities of this sort have been published<sup>17</sup>, stems from the need for understanding the origin of protein. This emphasis comports with Blum's 1955 analysis of the overall problem of origins. The approach which has developed in our laboratory was based on a back-extrapolation. The extrapolation was from data accumulated during investigations of Darwinian evolution at the molecular level, with proteins<sup>28</sup>.

The systematics of proteins can be examined in a number of ways<sup>28</sup>. One of these is through the perspective of the quantitative contents of unfractionated proteins of organisms throughout phylogeny (Fig. 1). The chart shown<sup>29</sup> reaffirms in a quantitative way the principle of the 'unity of biochemistry'<sup>30</sup>.

The other emphasis derivable from this investigation is that of the relatively high proportion of two amino-acids, the dicarboxylic amino-acids, aspartic acid and glutamic acid. This fact suggested the possibility that the generation of primordial protein relied on a relatively large proportion of the dicarboxylic amino-acids, a dominance which might persist in the record of molecular evolution in cells.

Focusing on the origin of proteins at that stage in the development of the theory of abiogenesis differed from investigations of the origin of amino-acids and of other micromolecules. We had been influenced in our thinking by the chemists' typical assumption that, whereas simple compounds require simple syntheses, complex compounds, for example, proteins, require complex processes. What now seems to be a more logical premise is that Nature would not have been able to accommodate a process as intricate as, for example, a carbobenzoxy synthesis and would have used instead some internally self-organizing simple process such as an appropriate type of

Fig. 1. Amino-acid compositions of unfractionated proteins of different organisms: (1) algae; (2) bacteria; (3) protozoa; (4) invertebrates; (5) mammals

polymerization. An additional reason for polymerizing amino-acids rather than analogues or derivatives is based on a recapitulationist premise<sup>28,31,32</sup>. This emphasis led to experiments different from those used as other models of formation of peptide bonds in the primitive world<sup>33,34</sup>.

The effort to use the presumed clue furnished by the moderately high aspartic acid and glutamic acid contents was based on heating in the dry state, for thermodynamic and other reasons<sup>35</sup>. When heat was used, a second scientific heresy was committed. The literature reveals that heating  $\alpha$ -amino-acids above the boiling-point of water typically yields diketopiperazines, amines and pyrolytic tars<sup>36</sup>. If one heats the amino-acids in the initially dry state and heeds the admonition from the evolutionary analyses, lightly coloured polymers having peptide bonds are, however, produced. These polymers can then be further purified by procedures which are standard for protein fractionation either by salting out from aqueous solution by ammonium sulphate<sup>37</sup> or on ion-exchange columns<sup>38</sup>. In order to obtain workable quantities of such polymers, at least one mole of dicarboxylic amino-acid per two moles of total neutral and basic amino-acid should be used.

An ultimate objective of these experiments was the simultaneous combination of all or nearly all the amino-acids common to contemporary protein. Comparative examinations suggest that the primordial

reactions must have embraced a maximum number of types of amino-acid. This inference is consistent with the fact that 'primitive' organisms contain all the contemporary amino-acids plus diaminopimelic acid<sup>39</sup>, and the genetic and biochemical reasoning which leads to the inference that a maximal variety of organic compounds was present in the primordial reaction<sup>40</sup>. Any method which would combine all the 18-20 common amino-acids could be expected easily to combine a smaller number. In addition, inclusion of all the eighteen amino-acids would provide a heteropolymer which, if it had a sufficient number of activities, might constitute (subject to definition) a synthetic general protein.

Many man-years of effort were, however, expended in systematic investigation of the thermal copolymerization of two or three amino-acids<sup>41,42</sup>. When the essential principle of thermal copolymerization was tested simultaneously on all the eighteen amino-acids common to protein<sup>43</sup>, it was found to apply to those circumstances also (Fig. 2). Some of each of the amino-acids was found in the polymer. This result was somewhat surprising against the background of knowledge that nine or ten of the amino-acids have reactive side-chains. The visualization of irreversible reactions of such side-chains was easy. However, thermal proteinoids which have undergone moderate purification can be hydrolysed by mineral acid and the contained amino-acids can be recovered quantitatively<sup>44</sup>. The conditions of the reaction, therefore, are not brutal, except for substantial destruction of serine and threonine; this is, however, largely controllable by use of a reducing mixture of hypophosphite and polyphosphoric acid<sup>45</sup>. The thermal copolymerizations and many of the analyses of the products have been repeated in other laboratories. These polymers were at the outset found to have, besides a complete qualitative roster of amino-acids, many of the properties of proteins. They are referred to as proteinoids, a term which originally indicated their similarity to proteins at the same time that it disavowed a claim of identity with contemporary protein. The possibility that the identity is great enough to allow regarding proteinoid as synthetic general protein is, however, in purview.

Typical reaction conditions are 170° C for 6 h. A 1:1:1-proteinoid, an example of one type of such polymer, is made from one part of aspartic acid, one part of glutamic acid, and one part of a mixture of the sixteen other amino-acids present in that part in equimolar proportions. As has been documented, temperatures of 170° C are terrestrially quite common<sup>46</sup>, yet the minimum temperature for polymerization within hours can be lowered to 65° by addition of appropriate phosphates to the reaction mixture. Yields of proteinoids, depending on conditions of reaction and degree of purification of product, typically range between 5 and 40 per cent. The higher yields are obtained with phosphates in the reaction mixture.

These conditions are closely similar to those reported from Schramm's laboratory and identical with ours for the polymerization of mononucleotides<sup>47</sup>. The fact that products as complex as proteinoids could be produced in a simple, and therefore geologically plausible, way suggested that polymers resembling polynucleotides might also be produced by simple heating. The characterization of thermal polynucleotides is, however, as yet, far less complete than that of the proteinoids.

In order to understand the essential processes which occur when amino-acids are heated, some of the special chemistry deserves examination.

The neutral amino-acids tend to undergo a head-and-tail condensation of two molecules to give a *cyclodipeptide* or diketopiperazine:

Fig. 2. a, Amino-acids heated above the boiling-point of water; b, ditto, with sufficient aspartic acid and glutamic acid, followed by purification by salting out

They also are decarboxylated to leave amines:

and more profound decomposition results in the formation of tar, as already noted.

Glutamic acid, however, undergoes an internal condensation in the single molecule to yield a lactam, pyroglutamic acid ( $\alpha$ -pyrrolidonecarboxylic acid).

When glutamic acid and a neutral amino-acid are heated simultaneously, they behave together in a way that is different from their individual behaviours.

The concerted heating yields unwanted products also, but it also yields genuine peptide-type poly- $\alpha$ -amino-acids, often as the major product with little discoloration or contamination by tar.

Aspartic acid participates in copolymerization in a manner which is different from that of glutamic acid. Aspartic acid yields a polymer which is a polyimide:

The residues may in part be  $\beta$ -linked as indicated:

for either or both the interior and N-terminal residues.

The polymerization of aspartic acid also permits bringing into polymeric combination amino-acids which would themselves undergo decomposition.

Most of the aspartic acid residues are in the imide form in (A). The hydrolysed A is the true peptide type of polyamino-acid instead of the imide type.

The basic amino-acids do not decompose as do neutral amino-acids; they also undergo thermal copolymerization. As stated before, all the amino-acids, including both dicarboxylic amino-acids and the three basic amino-acids, and the thirteen other  $\alpha$ -amino-acids common to protein, can be simultaneously copolymerized thermally. When the purified thermal proteinoid is

hydrolysed, quantitative recovery of the amino-acids which it contains is recorded, and one must conclude that irreversible reaction of functional side-chains cannot have occurred in a major portion of the raw polymer.

The basic amino-acids, especially lysine, are moreover capable of substituting for the acidic amino-acids in thermal polymerization<sup>48</sup>. Lysine can also be used for simultaneous thermal copolymerization of all the amino-acids to yield a basic lysine proteinoid<sup>49</sup>.

These results emphasize that the effect of simultaneous heating of amino-acids could not be predicted from homopolymerization or attempted homopolymerization. This difference between homopolymerization and copolymerization is consistent with the general experience of the polymer chemist. The polymer chemist, however, has not dealt with reactions involving eighteen monomers simultaneously. Accordingly, no precedent existed for the results of the present investigation. One may on this basis more easily understand a frequently observed first reaction of many chemists that such polymerizations can scarcely be reproducible or controllable, and that the polymers produced must be random in Nature.

Fig. 3 helps to answer this question. In Fig. 3 are seen three chromatograms, from the automatic amino-acid analyser, of three separate syntheses of proteinoids. These are three 2 : 2 : 1-proteinoids which differ in their synthesis and purification in one respect only. In b, the proportion of phenylalanine was the usual figure. In the experiment of a, all phenylalanine was omitted. In the experiment of c, the proportion of phenylalanine in the reaction mixture was 3.5 times that in b. Comparison of a, b and c reveals that the proportion of each amino-acid other than that of phenylalanine is quite constant. The thermal condensations of amino-acids are thus highly reproducible, as observed in many ways in other experiments. The proportion of phenylalanine is higher in the product from the reaction mixture containing a higher proportion of phenylalanine. Other experiments have shown that the proportion of an individual amino-acid in an acid proteinoid is regularly relatable to its proportion in the reaction mixture. The thermal polymerizations are thus quite controllable as well as reproducible.

The pair of proteinoids which differ by the absence of one amino-acid offer opportunities for investigation in protein nutrition. Some of the early nutritional biochemists such as Abderhalden and Mendel sought proteins lacking individual amino-acids so that they might examine the effect of individual amino-acids in protein nutrition. In this search they were doomed to failure because of the absence of such proteins in Nature. Instead, much of what we know we owe to W. C. Rose, who obtained the desired type of information by feeding first rats, then humans, with mixtures of pure amino-acids with systematic omissions. As Rose pointed out, such answers are imperfect in that caloric imbalances attend the feeding of amino-acids instead of protein<sup>50</sup>. In true protein nutrition, furthermore, amino-acids are gradually released from peptide bonds. In this respect the thermal proteinoids can function as synthetic proteins from which single amino-acids can systematically be omitted qualitatively and quantitatively. The question of nutritional availability of amino-acids from thermal polyamino-acids has been affirmatively answered for bacteria<sup>51</sup>, and for rats by Krampitz and Knappen<sup>51</sup>.

The question of molecular weights has been examined by end-group assay and by some analyses in the ultracentrifuge. Mean molecular weights of 3,000–10,000 have been recorded<sup>57</sup> for the acid proteinoids. These values may be compared with 6,000 for a small protein molecule, insulin. Since insulin has two end-groups, the figure for comparison is 3,000. Most proteins are considerably larger than 6,000, however; the molecular weights of the

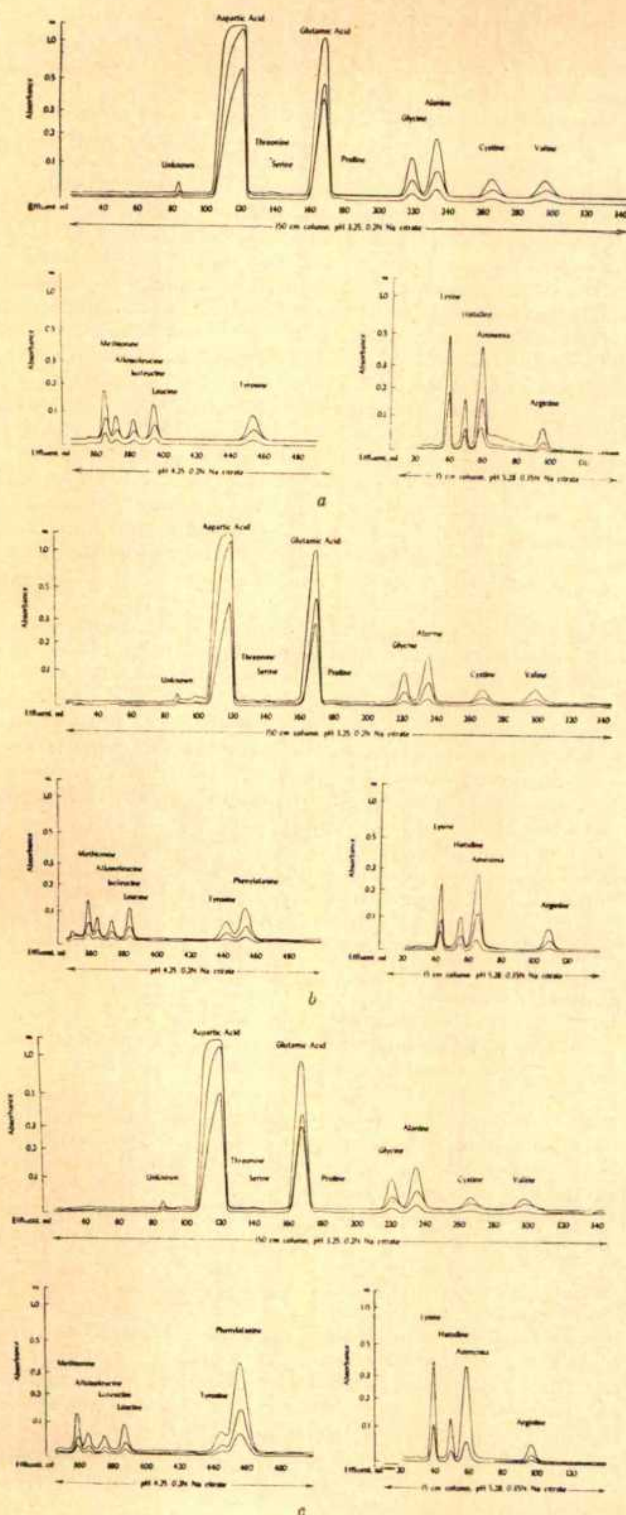

Fig. 3. Chromatograms of hydrolysates of proteinoids. *a*, 2:2:1-proteinoid reaction mixture lacked phenylalanine; *b*, standard 2:2:1-proteinoid; *c*, same as *b* with 3-5 times as much phenylalanine in the reaction mixture

proteinoids are thus in the lower end of the range of molecular weights of proteins. Cross-linking within the proteinoids is limited<sup>49</sup>.

A rigorous comparison of proteinoids with proteins cannot be carried out, because, like life itself, proteins are not rigorously defined nor rigorously definable. The variable nature of proteins precludes the possibility of a rigorous definition of those materials. Two descriptive definitions of proteins as a group can, however, be

cited<sup>52,53</sup>. The requirements of these definitions are met by the proteinoids as a class. The first of these requirements are the qualitative content of amino-acids and the molecular weights. In determining to what degree the complexities of protein molecules are mimicked by thermal proteinoids, many characteristics have been examined. These are outlined in Table 2. Missing from proteinoids as yet are the properties of antigenicity and helicity. They have not been assiduously sought in the proteinoids, however, nor are they universal properties of proteins. These properties are also found in synthetic polyamino-acids produced from Leuchs anhydrides<sup>54</sup>.

Non-random arrangements of amino-acid residues
Terminal residues and total composition
Sequences in fragments
Susceptibility to proteolytic enzymes
Nutritive quality
Catalytic activity
Morphogenicity

The property of non-randomness is investigated most meaningfully in an unfractionated polymer. While we are working towards determining an entire sequence, this kind of work needs to be done on homogeneous preparations. The sequence of residues in a homogeneous preparation cannot provide information on variation in sequence or composition such as had been determined in the experiments just described. The fact of non-random arrangements (repeatedly indicated by comparisons of total compositions, N-terminal and C-terminal compositions) betokens a measure of order in the synthesis. This order must be determined by the amino-acids themselves since almost no other material is present. Such a finding is of evolutionary significance when viewed against the

Fig. 4. Coacervate droplets from gelatin, gum arabic and ribonucleic acid (after Oparin). ( $\times 240$ )

Fig. 5. Proteinoid microspheres prepared by allowing hot solution of proteinoid to cool. These units are approximately  $2\mu$  in diameter

background of recognizable order in organisms. The thermal proteinoids, as a model of abiotic polymer, demonstrate how the beginning of order could have developed at a molecular level in a pre-biological period. Since no genetic nucleic acid is present in the reaction, the degree of ordering that is found is ascribed to the internal influences of the amino-acids themselves. Such an effect can be understood in terms of the specific shapes and charge distribution of each of the eighteen types of amino-acid. The concept that order could have been partly specified by the primitive protein itself is substantiated by investigations of Pattee<sup>55</sup>, based on computer theory. The principle of internal self-direction is fundamental to general evolutionary theory<sup>56</sup>.

The conceptual possibility that pre-biological protein molecules might have arisen before pre-biological nucleic acids can be more seriously entertained in the light of the demonstration of internal self-control of sequence. Three properties which, in pre-vital protein, would be of first significance to organisms that might evolve therefrom are: service as proteinaceous food, catalytic activity and any tendency to form microstructures having boundaries with membranous properties. The first of these activities, in proteinoids, has been mentioned.

Catalytic activity in proteinoids was first observed for the unnatural substrate, *p*-nitrophenyl acetate<sup>49</sup>. Rohlfs<sup>56</sup> has shown that the relatively high activity observed is due to the simultaneous presence in the proteinoid of histidine residues and of aspartimide linkages. As the imide linkage is progressively opened (by mild treatment), the catalytic activity is also progressively decreased. The imide type of polyaspartic acid, without histidine, is devoid of activity.

A second type of catalytic activity which has been observed is found in proteinoids which have been suitably reacted with zinc. Inorganic salts of zinc are known to catalyze the hydrolysis of ATP at 80° (ref. 57). When zinc hydroxide gel is reacted with acid proteinoid, the resultant zinc-proteinoid is active in the hydrolysis of ATP at 40°. This effect, in conjunction with organized units, is later described more fully. Activity by combination with zinc can be viewed as an experimental model of a first step in the conceptual evolution of a metal-enzyme<sup>58</sup>.

A third type of catalytic activity is that which has been shown to enhance the decomposition of glucose to gluconic acid, carbon dioxide, and other products<sup>59</sup>.

Although this is a weak activity, no more than weak activity was needed in the first proteins. Furthermore, among the numerous activities now being catalogued for the proteinoids, some are considerably stronger. The essential feature is the occurrence in macromolecules of significant catalytic activity such as might launch a primordial, biochemically active, cell.

To this point, one can in any event visualize, on a basis of sequentially compatible reactions demonstrated in the laboratory, the thermal conversion of amino-acids to a primitive kind of protein.

In a coherent theory of origins, the manner in which primitive protein might modulate to primitive cells is one of the next questions.

The kind of experiment to which the biochemist, A. I. Oparin, has devoted major effort is that of the multi-molecular systems, or, more interpretatively, models of precellular organization. Oparin is properly credited with promulgating a natural origin of biochemical systems through organic chemistry<sup>4,5</sup> at a time when naturalistic explanations were not available. Equal credit is deserved by Oparin for his emphasis on the need to understand self-organizing phenomena yielding the first cells. George Wald<sup>10</sup>, and others, have also added explicitly to the theoretical underpinnings.

Oparin's experiments have used as a model of precellular organization the coacervate droplet introduced by the colloid chemist, Bungenberg de Jong<sup>60</sup>. Some of these are illustrated in Fig. 4. They can be seen to be microscopic, and not uniform. Oparin has concentrated enzymes and substrates within coacervate droplets. The presence of organization allows reactions to proceed in a concentrated fashion, apart from the environment. The value of packaged reactions in a unit which has separated from the pre-environment is that such a unit could then evolve metabolically along with the development of internally associated reactions.

Oparin has pointed out one defect of this model—the lack of stability. The coacervate droplet made from gelatin and gum arabic cannot withstand gentle centrifugation or some concentrations of salts without breaking down into two liquids. As Oparin has stated, the coacervate droplet would in an evolutionary way have to develop stability before it could function as a valid model of the late stages of precellular organization<sup>61</sup>. Another defect as a precellular model is the reliance for structural purposes on protein of recent origin such as gelatin.

From the thermal polyamino-acids, including thermal proteinoid, an alternative model emerges (Fig. 5). This model differs crucially from typical coacervate droplets and from other cell models<sup>62</sup>, in that the structural material is not a polymer from contemporary organisms. The material is instead a protein-like polymer which arose from simpler units, amino-acids, which can be formed and combined, as has been shown, by a kind of experimental geosynthesis. Another significant difference resides in the fact that the formed units have stability comparable to that of many contemporary cells. They withstand centrifugation in a clinical centrifuge. As first shown by Dr. Richard S. Young<sup>63</sup>, they are stable enough to be sectioned, allowing electron microscopy<sup>64</sup>, as represented in some of the photographs in this article.

The manner in which the proteinoid microspheres arise is yet simpler than that by which the polymer emerges. Water or various aqueous solutions are added to the hot polymer mixture, the hot clear solution is decanted and, following a few minutes of cooling, vast numbers of individual microspheres are seen to separate. It is possible also to use cold purified proteinoid by heating the suspension produced when water or aqueous solution is added to the solid. In some preparations, the propensity to form microspheres is so great that the units appear on mere contact of cold water with cold proteinoid.

The size is microscopic, those in Fig. 5 being slightly less than  $2\mu$  in diameter. This is then the size and shape

Fig. 6. Optical micrograph of microspheres. Fine details of structure may be noted

of the coccoid bacteria, which have been regarded by Kluyver and van Niel, and Lipmann<sup>65</sup>, as the most primitive of the bacteria.

As can be seen in Fig. 5, the spherules can be produced in a uniform size. This picture, however, demonstrates some of the variations in shape. The uniformity which is obtainable permits quantitative experiments. When transferred to solutions hypertonic or hypotonic to those in which they were made, the microspheres shrink or swell correspondingly<sup>66</sup>. This kind of behaviour is manifest at concentrations of salt much higher than those necessary for the demonstration of osmotic effects in true cells. What is seen, however, may be the basis for a kind of primitive osmometer<sup>67</sup>.

Another figure of interest is the simulated budding. In addition, 10 mg of proteinoid yields more than  $10^7$  microspheres. In the context of natural experiments, the appearance of this numerosity emphasizes, in addition to the number of experiments in vast numbers of individual locales, a very large number of experimental individuals per experiment. A single terrestrial experiment on a geological scale would be much larger than what can occur with 10 mg of thermal polymer.

Fig. 6 shows some larger microspheres, in which more anatomical detail is apparent than in Fig. 5. What looks like concentric shells, or a kind of double layer, may also be seen. One cannot be sure of this observation inasmuch as it is the result of optical microscopy. Apparent also are some filamentous particles. These are not lint or other result of unclean microscopy. They are associations of microspheres from a second population of smaller units, which are barely visible. These latter are quite uniform in size; their diameter is the same as that of the filaments. The filaments, on close examination, are seen to be segmented associations of the small microspheres. These structures, like the 'buds' and microspheres, are provocative in the

context of biomorphology. Only the microspheres have so far been extensively investigated.

Knowledge of the composition of the proteinoid has permitted using them as a model unit in investigation of cytochemical staining. In 1924, Stearn and Stearn attributed the Gram stain of bacteria to the acceptance of the stain by structural protein of the bacterial cell<sup>68</sup>. Because of the protein-like nature of the material composing the microspheres, the latter were tested for their acceptance of the Gram stain. The possibility that they could be used also for explaining the difference between Gram-negativeness and Gram-positiveness also suggested itself. Of the many theories of this difference, the recent concept that the difference depends on the proportion of basic biopolymer invited attention<sup>69</sup>.

The first finding was that, consistent with the stipulation of Stearn and Stearn, the typical microspheres of proteinoid accept the Gram stain; they are Gram-negative. To test the possibility that basic polymer might influence the sign of the stain, the lysine proteinoid

Fig. 11. Twinned proteinoid microspheres observed in suspension in which pH has been raised

mentioned earlier was used. Lysine proteinoid does not form microspheres in the manner that the acid proteinoid does. Mixture of lysine proteinoid and acid proteinoid containing less than 60 per cent of the former polymer will form microspheres which contain the latter. If the proportion of lysine proteinoid in the mixture exceeds 35 per cent, the microspheres stain Gram-positive (Fig. 7). Although this use of the model does not rule out other explanations, further consideration of the Gram stain must take such results into account, particularly since the results in the model are not subject to confusion by a number of other metabolites. The solubility of the Gram-negative microspheres in dilute alkali and the virtual insolubility of the Gram-positive type furthermore parallel quite exactly the solubilities of the Gram-negative and Gram-positive bacteria<sup>69</sup>, respectively.

The morphologies of the various micro-particles, inadvertently obtained, bear remarkable resemblances to almost all the meteoritic 'formed elements'<sup>70,71</sup> which have been published. Comparisons of three of these are shown in Figs. 8-10.

In Fig. 10 can be seen a formed element undergoing 'cell division' while it is being constricted at the middle, as pointed out by Claus and Nagy. On the right is a micro-particle from a laboratory experiment. The same features are brought out more clearly. In this case, the microspheres originally formed have been treated under the cover-glass with a few drops of buffer of pH 5.5-6.5, the original pH being approximately 3.0. Evidently some redistribution of charge is responsible for the re-arrangement of structure.

These comparisons pose the possibility that the 'formed elements' were at no time alive, rather that they were natural physico-chemical experiments which terminated before life emerged<sup>72</sup>. If so, they are of profound interest in a context of molecular evolution.

These similarities also are consistent with the inference that the laboratory experiments are closely akin to natural experiments. The thermal gradients and moisture which are present in the carbonaceous chondrites during their trips into the Earth's atmosphere<sup>73</sup> would provide the necessary conditions. Of related interest is

the inference by Kaplan *et al.*<sup>74</sup> that the types of carbon compounds which occur in organisms may be formed in meteorites.

One of the clearest pictures showing microspheres simulating cells in cleavage is that of Fig. 11. This picture has been mistaken often enough by biologists to be a field of dividing bacteria that the question has properly been asked if the view is not indeed one of contaminating bacteria in the process of division. That the particles in such views are synthetic is shown by the fact that they arise in periods of less than 2 h, and the fact that they can be redissolved by warming the microscope slide. In this picture may also be seen the small microspheres, and the filamentous associations thereof. A particularly provocative question in this case is the one of whether the particles which appear to have cleaved are the products of fusion or fission.

This question has been answered for some years as a process of fission. The first documented experiment is presented in the frames from a time-lapse sequence reproduced in Fig. 12. The change between the second and third frames in the mount clearly shows the formation of a septum and of two centres. This kind of cleavage simulates the type of division observed in the septate cocci<sup>75</sup>.

This time-lapse sequence also illustrates other phenomena. When the initial solution of proteinoid is heated for many minutes instead of the usual few seconds, the particles are not uniform; hence, the large microsphere near the centre of the frames. The sequence of photographs shows the progressive disappearance of the centre of the larger microsphere. In many experiments this centre has disappeared entirely but the boundary

Fig. 12. Frames from a time-lapse series showing cleavage

Fig. 13. Electron micrograph of proteinoid microsphere which has been stained with osmic acid, and embedded in a methacrylate block which was cured and sectioned

remains. Such a phenomenon poses a provocative chemical question of the difference between the visually unchanged boundary and the interior of the unit. Analyses have as yet shown no difference in amino-acid composition.

This behaviour is part of the evidence indicating that the kind of selectivity necessary for a primitive membrane is a property of these units<sup>75</sup>. The boundary appears to remain unchanged through the experiment, yet the interior, made up also of proteinoid, passes out through that boundary. The absence of material in the interior while the boundary persists is corroborated by some of the electron micrographs.

The first of the electron micrographs (Fig. 13) shows a single microsphere which has been stained with osmic acid, trapped in methacrylate which was cured, and sliced by microtome<sup>76</sup>. The sections in this treatment tend to be 800 Å thick. Although some bacteria reveal more structure than this to the electron microscope, some do not. A section of *Bacillus cereus* micrographed and reproduced in the treatise on *The Bacteria* is comparable<sup>77</sup>.

Fig. 14 shows five microspheres caught in a suspension<sup>76</sup>. In this case, the pH has been raised. Four of these illustrate various stages in the outward diffusion of the polymer from the interior. Several of them show very clearly a boundary.

Fig. 15 depicts more microspheres subjected to raised pH. Two fields are placed side by side here to show a progression in one phenomenon. This is the double layer, analogous to the double membrane of true cells<sup>78-83</sup>. This phenomenon had not been sought. If, however, a model of cellular origins had some validity, unsought features should occasionally appear. Recent thinking has emphasized the presence of phospholipid between the protein layers of a double membrane<sup>84</sup>. In this case, comparable chemical character might be attributed to the hydrocarbon side-chains of the amino-acid residues in the proteinoid. The double layer has been known to retain its structure after extraction of the lipid<sup>79</sup>, and recently Green *et al.*<sup>85</sup> have reported that the layering within mitochondria is undisturbed when the lipids are extracted from the mitochondria by aqueous acetone; they have

identified 'structural protein'. This kind of emphasis is consistent with the finding of double layering from proteinoid alone. These results and those with the Gram stain suggest that the emphasis in the introduction on experimenting with the conceptually simplest natural experiments can be extended. Such simple experiments can help to control investigations of complex phenomena in living cells when fewer than all the associated natural materials or processes in the living cell can be identified as pertinent.

Attempts to produce metabolizing microspheres have focused on introducing catalytically active cations, a conceptual possibility in view of the chemical structure of the proteinoids. Investigations have narrowed to zinc, which has been known to catalyse the hydrolysis of ATP in aqueous solution at 80° (ref. 57). Following many trials, zinc was introduced by reacting zinc hydroxide gel with proteinoid in suitable ratios in hot aqueous solution for 4 min. The hot clear solution deposits microspheres containing typically 1-3 per cent of zinc. The first two aqueous wash liquids show some activity, but the third through fifth washes reveal scarcely more activity than is found in the ATP spontaneous hydrolysis control, signifying the removal of zinc adhering to the microspheres (Fig. 16). The zinc-containing microspheres retain, however, substantial ATP-splitting activity. Cellular phosphatases often contain magnesium, but some of them contain zinc<sup>86</sup>. The level of activity in the microspheres is undoubtedly much weaker than that in a natural adenosine-triphosphatase. As Calvin has pointed out theoretically for iron-containing enzymes, weak activity would have been sufficient in the early stages of life<sup>87</sup>; evolution would have selected the more powerful enzymes that we find in contemporary cells.

With ATP-splitting activity localized in this fashion, visualization is possible of how a thermal synthesis of primitive protein might have modulated to the first steps towards a primitive ATP-dependent cellular synthesis of protein. Regardless of how much like the proteins the thermal proteinoids may be, the mechanisms of synthesis are energetically different. If thermal synthesis led to

Fig. 14. Five proteinoid microspheres treated as for Fig. 13

Fig. 15. Double layers in sections of proteinoid microspheres. This electron micrograph confirms optical evidence of Fig. 6

pre-protein, some modulation to a cellular type of synthesis was necessary.

The simulation of so many pre-biochemical steps by heat calls to mind the fact that the organic chemist in his laboratory usually finds heat to be most convenient for carrying out his reactions. Fundamentally, a principal reason is that many organic reactions are energized by volatilization of product water. The same explanation pertains to spontaneous geosynthesis. What then are suitable thermal locales on the Earth?

Many suitable locales for spontaneous thermal geosynthesis can be proposed at present<sup>46,47</sup> and geological theory suggests that this number may have been even greater in earlier times<sup>48</sup>. One can visualize that amino-acids might form directly from intermediates produced in vapour phase reaction in a volcanic region, according to the conditions specified by Dr. Harada's experiments. Enough water would have to enter the scene to promote hydrolysis of the amino-acid intermediates. Frequent hydrolysis and evaporation require no conceptual strain if one thinks of the frequency of rain in volcanic regions, as elsewhere. A deposit of amino-acids in a region of 100–200° would promptly yield pre-protein-like polymers to the extent that aspartic acid<sup>47</sup> and glutamic acid were present. A second possibility is that amino-acids might be formed in the atmosphere and then rain in the dry state on to hot volcanic areas. A third possibility is one of an oceanic soup of amino-acids of any concentration. When some of this would splash on to seaside lava beds (many volcanoes are near the sea) the water would evaporate very quickly if the amount splashed were small. The solid residue after evaporation would then consist of dry amino-acids. A fourth possibility is one in which the amino-acids in any of these ways, or in any other, came into contact with warm or hot phosphate beds<sup>49</sup>. Lesser temperatures could suffice for polymerization. The necessity of a proper balance of amino-acids continues to apply, however.

Any or all of these circumstances should have operated for the geosynthesis of pre-protein; probably other conditions were suitable as well. So far, other modes of

producing peptide bonds in the laboratory under quasi-geochemical conditions<sup>34,40</sup> have shown predominantly glycine in the polymer; glycine is one amino-acid which has long been known to undergo homopolymerization readily<sup>36</sup>. Reliance on recovery of small amounts of other amino-acids following hydrolysis does not support a statement that heteropeptides were formed, inasmuch as hydrolysable diketopiperazines form readily<sup>35,36</sup>. Quasi-geochemical methods of producing in water polyamino-acids with substantial proportions of many amino-acids which are surely bound as peptides may, however, yet be found. The first demonstration of how peptide bonds may have formed yields polymers remarkably like proteins (Table 2).

The geological conversion of such polymers to microspheres functioning as pre-cellular forms would be similarly simple and, according to the experiments, bound to occur in innumerable places on innumerable occasions. The requirements for the geosynthesis would merely be the intrusion of water and the inexorable tendency of such polymers to form cell-like units, as already demonstrated in the laboratory. Inasmuch as the sequence of reactions from primordial gas to microspheres under water is shown to occur in only hours, the organic material composing, or trapped in, the microspheres would be protected from destructive action of heat or other radiation by the overlying layers of water. When one recognizes the breadth of conditions under which the reactions occur and the breadth of terrestrial occurrence of these conditions, one must infer a truly tremendous number of natural experiments. Superposed on this picture is a huge number of microspheres in each experiment, with obviously some variation in individuals.

In biological evolution, selection is believed to be the major process<sup>51</sup>. The possibility of an internal limitation in the step of diversification preceding selection does not receive much serious attention<sup>51</sup>. An effect of this sort is, however, indicated for the molecular evolution which is modelled by the chemical experiments. When organic compounds are produced by imparting various types of energy to various mixtures of simple compounds of carbon, hydrogen, oxygen and nitrogen, the compounds formed tend to be predominantly amino-acids. This preference can be understood on the basis that amino-acids are inner salts; as inner salts they are relatively stable and are thus favoured<sup>57</sup>. Just as amino-acids are favoured over other organic compounds, certain amino-

Fig. 16. ATP-splitting activity of washed zinc-containing microspheres from Fox, Joseph and Wiggert, *Origins of Prebiological Systems* (Academic Press, 1965)

acids result more easily and more often than others. Certain polyamino-acids would also be favoured over others for purely chemical reasons. If one believes that chemical processes operate in cells, we can anticipate that self-limiting diversification<sup>2</sup>, as well as selection, operates in bio-evolution. The picture, then, would be one of self-limitation in diversification spanning the pre-biological and the biological. In the biological era alone, selection would operate in addition.

The thermal model has developed from a pluralistic philosophy which uses contemporary biology for clues and as a framework of testing and uses experimental 'geosynthesis' primarily as a laboratory technique. A pluralistic philosophy of this sort has seemed necessary inasmuch as we cannot extrapolate back to a prebiotic system in a manner that is in the usual sense testable. This follows, of course, from our ignorance of what the prebiotic system or systems were. Complete knowledge of contemporary biochemical systems may prove to be useless, or even inhibitory or misleading for the purpose of understanding or synthesizing a prebiotic system. On the other hand, a sufficiently disciplined theory of pre-biological chemistry must prove eventually to be fundamental to biological chemistry.

Once research seems to have found its way on to the track which produces relatively simple prevital systems, further experiments can be directed at introducing in a stepwise manner additional characteristics of biocells in a naturalistic and empirical (albeit now guided by the experimental evolutionist) manner.

On the whole, research of this sort generates new questions faster than it does answers; but some answers are forthcoming. The possibility of understanding how materials as complex as proteins or nucleic acids might have arisen in a manner that is sufficiently simple to have occurred spontaneously on the primitive Earth is demonstrated by experiments.

The protein-cell-protein dilemma expressed by Blum and by others<sup>92,93</sup> is resolved by these experiments, as are other dilemmas. Protein of properties adequate to forming primitive protocells could have arisen without a living system to produce them; all that was needed was the necessary primordial gases forming amino-acids in suitable proportions, and heat. This kind of protein not only could form; our investigations in the field<sup>46</sup>, in the laboratory, and in the library indicate the occurrence of multitudinous geological possibilities. In this view, one can more easily visualize a large number of natural experiments of which one or more would happen to include the biochemical apparatus necessary for continuing replication. When that occurred, a first primitive cell would have emerged, and the entire parade of Darwinian evolution could begin.

A similar kind of dilemma is that posed by the need to visualize genes as arising before cells<sup>94,95</sup>. The demonstrated self-ordering properties of geosynthetically derivable macromolecules are such that we can now more easily visualize the origin of the cell before or simultaneous with the emergence of primordial nucleic acids<sup>75,96</sup>. We might refer to these synthetic polyamino-acids as morpho-molecules to emphasize the degree to which the visible structure of the particles is a manifestation of the nature of the molecules<sup>10,75,97</sup>.

The significance of any step in the thermal model is a function of the significance of the total model and *vice versa*. The larger theory is such as to permit us to visualize, through the discipline of experiments, how primordial gases could be spontaneously converted to amino-acids, these in turn to protein, and this latter to a membranous microparticle having many of the properties of cells, including the tendency to divide and to metabolize. If the pond is deferred, the visualization is then a detailed demonstration of Charles Darwin's now well-known statement<sup>67</sup>:

"It is often said that all the conditions for the first production of a living organism are now present, which

could ever have been present. But if (and oh! what a big if!) we could conceive in some warm little pond, with all sorts of ammonia and phosphoric salts, light, heat, electricity, and carbon present, that a proteine compound was chemically formed ready to undergo still more complex changes . . .".

Any remaining discontinuity between non-life and life should, according to present understanding, be regarded as not yet understood rather than as hopelessly incomprehensible. We may even adopt the position that, while we credit Darwin with that insight into pre-biological molecular evolution, we owe him more for presenting the principle of biological evolution, inasmuch as the later processes will in the long run prove to have been composed of more intricate and subtle sets of transformations.

This theory is derived from the efforts and critical discussions of numerous associates. The work was supported by grants from the U.S. National Aeronautics and Space Administration (NSG-173-62), the U.S. Public Health Service (C-3971), the National Science Foundation, the General Foods Corp., Eli Lilly and Co., and the Rockefeller Foundation.

## CONSEJO SUPERIOR DE INVESTIGACIONES CIENTIFICAS, SPAIN TWENTY-FIFTH ANNIVERSARY CELEBRATIONS

IN 1939, soon after the end of the Civil War, the Spanish Government set up the Consejo Superior de Investigaciones Cientificas for the purpose of fostering, directing and co-ordinating research in both the sciences and the humanities. During the week beginning on October 18, 1964, the Consejo celebrated its twenty-fifth anniversary by arranging a solemn opening session, scientific meetings, and certain social events; and it invited a number of foreign guests to attend.

The Consejo is divided into eight "patronatos", grouped together to form three main sections: the Division of Humanities, the Division of Sciences, and the Patronato of Scientific and Technological Research which deals with applied science. It is responsible for a large number of institutes, many, but by no means all, of which are in Madrid.

It is at first sight somewhat surprising that it was necessary to create a new organization, and one which, though under the Ministry of National Education, enjoys a considerable degree of independence, to foster the type of research which in most countries is regarded as appropriate to universities. Spanish tradition, however, in contrast, for example, with that of Germany, has hitherto regarded the universities primarily as places of professional training rather than as centres of learning and research; and if the necessary rapid progress were to be made some organization outside them was necessary. The progress made by the Consejo in its twenty-five years, the quality of the research which it is organizing, the influence which it is beginning to have on the outlook of the universities, and the impetus which it is giving to Spanish technological development all demonstrate the wisdom of the original decision to set it up and the competence with which its activities have been developed.

The celebrations began with a solemn inauguration on October 20 in the presence of the Head of State, at which

messages of congratulations from international and foreign organizations were delivered. Thereafter, except for unified social events, the proceedings were broken up into five colloquia. That organized by the Division of Humanities dealt with problems of Spanish art and history, and with linguistic questions, and had a very largely Spanish attendance. That organized by the Patronato of Scientific and Technological Research on the theme "Research and Industry" was mostly conducted in Spanish, but included papers by D. R. Vieweg (Germany) on staffing problems, by D. L. Jacqué (France) on programming of research, by D. R. R. Adams (United States) on the measurements of the profitability of research, and by D. E. Martindale (Great Britain) on scientific information. The eleven introductory papers led to much discussion, and some sessions were very lively: notably that in which the question was discussed whether university professors ought to be expected to do research.

The remaining three colloquia were organized by the Division of Sciences, and took on a more fully international character, though naturally with very considerable Spanish attendance and participation. Two were in the biological field, on current problems in biology and on the contributions of ecological and agricultural research in the world fight against hunger. The third dealt with the physical chemistry of processes on solid surfaces.

The colloquium on "Current Problems in Biology" covered a wide range of subjects; some of the contributors discussed in detail a small facet of a biological problem, and others attempted a wider conspectus of a particular field. The opening colloquium on the organization of biological investigation was largely directed to problems of organization and financing of biological research in Spain. The more general conferences were inaugurated by Dr. R. Stanier (United States), who dis-

Dr. Hoare has taken an active part in the administration of the University; he represented the Faculty of Science on the Court from 1950 until 1952, held office as Dean of the Faculty of Science from 1958 until 1961, and has served as an additional member of the Senate for the periods 1960-62 and 1964-65. He is a member of the Council's Advisory Committees on the Education and Training of Non-academic Staff and on the Welfare of Clerical, Technical and Maintenance Staffs. During his time at Leeds he has initiated investigations at very low temperatures and has built up the facilities for this work with particular reference to the properties of metals and alloys. He has published many papers on the thermal and magnetic properties of the transition elements and is the author of an undergraduate text-book on thermodynamics as well as part author and co-editor of a reference book on low-temperature techniques.

### Development of Nuclear Power in Britain

In a written answer in the House of Commons on December 1, the Minister of Power, Mr. F. Lee, said that the Government proposed to keep the further development of the British Nuclear Power programme under review as envisaged in the White Paper on the Second Nuclear Power Programme. The question of the type of reactor to be included would be considered when the results of the enquiry for tenders for the first station in the programme were available in 1965. In reply to a further question on December 8, Mr. Lee offered no further information, but the position of the electricity, gas and nuclear energy industries generally was raised in the House of Lords on December 8. Lord Hawke pointed out that capital costs had been coming down and were now about £40 per kW for conventional stations.

In reply for the Government, Lord Stonham said that the Government fully recognized that Britain's economy and planned expansion were dependent on the production of power and that the fulfilment of a policy to meet that demand efficiently and economically required investment on a massive and increasing scale. In 1963 the gas industry in Great Britain spent more than £90 million on capital account, and the nationalized electricity industry in England and Wales, including nuclear power stations, spent almost £490 million. The annual capital expenditure in the electricity industry was expected to increase substantially, and a figure of £673 million had been approved for the next financial year. Capital investment by the Gas Boards was not expected to be more than about £100 million a year, but it was impossible to give precise forecasts until the Government's present review of public expenditure and investment had been completed. It was certain, however, that the £770 million expected to be invested over the next year in gas and electricity would be insufficient if in the years ahead the growth of the economy were to be supported and domestic requirements met. The Generating Board's proposals should give a reserve margin of plant by about 1970 of some 17 per cent, and this would involve investment totalling £4,000 million over the next six years. Lord Stonham went on to point out that nuclear plants would play an increasingly important part, but the present nine stations were of the magnox type; the tenders which had been invited for the advanced gas-cooled reactor type could not be expected until well into the summer of 1965. Little hope could be held out for great expansion in regard to pump storage, although pump storage stations had a longer working life than conventional generating plants. Further advances in the technology of conventional generation might, however, make pump storage schemes more attractive, as would the growing availability of nuclear power when the capacity of nuclear power plants was sufficient to supply the minimum load on the system and surplus low-cost nuclear energy was available for night pumping. Lord Sherfield thought that the target of 5,000 MW of additional nuclear power by 1975 was on the low side,

although he agreed that there were difficult questions of priorities and national interest. He urged the importance of firm decisions, while Earl Ferris referred to the necessity of spending much more money on research into the possibility of laying underground cables more cheaply and more effectively, as was being done in other countries.

### Future of Teacher Training Colleges in England and Wales

In a statement in the House of Commons on December 11, the Secretary of State for Education and Science, Mr. M. Stewart, said the Government had now considered the recommendations of the Robbins Committee on the future of the teacher training colleges in England and Wales. The Government agreed that wider opportunities should be given to suitable teacher training college students to take a degree together with a professional teaching qualification by means of a four-year course. However, after considering the advice given by the University Grants Committee, the Government had concluded that the academic and administrative and financial aspects were separable and that fundamental changes should not, at the present time, be made in the administrative and financial structure of the teachers training system. It had therefore been decided that the colleges should continue to be administered by the existing maintaining body under the present system of overall supervision, but the present arrangements for the internal government of colleges would be reviewed forthwith by all those concerned, in the light of the recommendations of the Robbins Committee. It had been agreed that the training colleges could appropriately be renamed 'Colleges of Education'. Mr. Stewart believed that the colleges should have a proper measure of independence in academic matters, and he thought that it was particularly important that local authorities should attend to this.

### Overseas Development

In reply to questions in the House of Commons on December 15, the Minister of Overseas Development, Mrs. B. Castle, said that about 550 in the direct employment of her Department, including specialized project advisers, were expected to be serving overseas in 1965; some 140 could be attributed to functions of the Department of Technical Co-operation. The Commonwealth Development Corporation was being transferred to her Department, and when this was completed she would review the functions and resources of the Corporation in the light of the needs of the British aid programme as a whole. Arrangements already existed for the co-ordination of educational assistance under technical co-operation arrangements and through the British Council, and this co-ordination would be strengthened. The annual rate of appointment of qualified technical staff for Commonwealth Africa had been more than doubled since 1962 and a thorough review of recruitment policy generally had been commenced. Total assistance from Britain to the less-developed countries in 1963 was estimated at £227.8-£247.8 million compared with £273.9 million in 1961 and £218.3 million in 1962. Of the 1963 figure, bilateral economic aid was £138.9 million and private investment £70-90 million.

### Joint Study of Natural Gas Pipeline across the North Sea

SIR HENRY JONES, chairman of the Gas Council, stated in London on November 30: "The Gas Council and N.V. Nederlandse Aardolie Maatschappij (Gas Export) have agreed to initiate a joint study of the technical and economic aspects of a natural gas pipeline from the Netherlands to Great Britain across the North Sea. The study will enable work which has hitherto been performed separately to be continued in more detail. It does not indicate any commitment by either party to supply or to take gas at any future date".

## University of Saskatchewan Linear Accelerator Laboratory

THE University of Saskatchewan Linear Accelerator Laboratory was officially opened on November 6, 1964. More than one hundred European, American and Canadian scientists attended the ceremonies, and sessions of contributed and invited papers were held. This occasion marked the bringing into operation of a linear electron accelerator with 140-MeV maximum unloaded energy and a mean current of 200  $\mu$ amp at 100 MeV. The energy can be varied continuously from 5 MeV to its maximum value. Pulse durations from 5 nsec to 1  $\mu$ sec are available at a repetition rate of 0-1,400 pulses/sec. The energy spectrum at the output of the accelerator is about 2 per cent. The director of the Accelerator Laboratory is Prof. L. Katz.

## Biology at Euratom

A REPORT of the European Atomic Energy Community, entitled *Euratom's Biology Programme 1961-64: Report and Perspectives*, by R. K. Appleyard, describes the progress and growth of the Biology Division since its inception three years ago (Pp. 37. (EUR. 1884. e.) Brussels: European Atomic Energy Community—Euratom, 1964). The report is divided into three parts dealing briefly with administrative and political factors and more fully with the scientific programme of the Division. The basic policy of the Division is to encourage research by contractual arrangements with individual institutes or centres of research within the six member countries and to act as a centre for community effort within the field of radiobiology. Financial resources, and the uses to which they were put, are described in some detail, both within the text and by tables and diagrams in the appendixes. Direct research activities of the scientific staff of the Division were chiefly limited to investigations of environmental contamination and the movement of isotopes in ecological systems. Work done under contract was much more broadly based, however, and represented the greater part of the expenditure of the Division. One avowed aim of the support of outside work was to "encourage not only original ideas but new growing points of research activity and enhanced responsibilities among younger research workers". The latter intentions did not seem to be reflected in the contractual programmes listed in Appendix 3. The rate of accumulation of publications from the activities of the Division was also shown in Appendix 3. Although the total yield of publications was impressive, a list of selected literature would have been more instructive.

## Yale Arbovirus Research Unit

THE Rockefeller Foundation Virus Laboratories moved in December 1964 from New York to New Haven, Connecticut, where the virus research programme of the Foundation will be associated with the Department of Epidemiology and Public Health of Yale University as the Yale Arbovirus Research Unit. Dr. W. G. Downs, director of the Foundation's virus programme, and Dr. M. Theiler, former director of the Laboratories, have been appointed professors in the Yale University School of Medicine. Dr. L. Whitman, acting director of the Laboratories, Dr. Sonja M. Buckley, Dr. J. Casals-Ariet, Dr. Delphine H. Clarke, and Dr. R. W. Speir, of the staff of the Laboratories, will also have faculty affiliation. In New Haven the Laboratories will be located, in a new building recently completed for the Department of Epidemiology and Public Health, at 60 College Street.

## Journal of Applied Ecology

RECENT developments in the expanding field of ecology have stimulated the British Ecological Society to publish a third journal to supplement their two existing journals, the *Journal of Ecology* (started 1913) and the *Journal of*

*Animal Ecology* (started 1932) (*The Journal of Applied Ecology*, 1, No. 1, May 1964. Edited by A. H. Bunting and V. C. Wynne-Edwards. Pp. vi+218. Oxford: Blackwell Scientific Publications, 1964. Published twice a year, 70s. net. Annual subscription, post free, 120s., U.S. and Canada, 20 dollars). The first number contains sixteen papers and several book reviews. Six titles suggest something of the range of subjects covered: J. N. Black, "An Analysis of the Potential Production of Swards of Subterranean Clover (*Trifolium subterraneum* L.) at Adelaide, South Australia"; A. D. Ansell, K. F. Lander, J. Coughlan and F. A. Loosmore, "Studies on the Hard-shell Clam, *Venus mercenaria*, in British Waters"; Donald A. Spencer, "Porcupine Population Fluctuations in Past Centuries revealed by Dendrochronology"; F. H. W. Green, "A Map of Annual Average Potential Water Deficit in the British Isles"; G. Szeicz, J. L. Monteith and J. M. dos Santos, "Tube Solarimeter to Measure Radiation among Plants"; David Jenkins, Adam Watson and G. R. Miller, "Predation and Red Grouse Populations". The contributors, editors, publishers and printers are all to be congratulated on the high standard of presentation in this first number. Further numbers will help to clarify the exact scope of this new journal in relation to its older stablemates.

## The British Journal for the Philosophy of Science

THE purpose of the British Society for the Philosophy of Science is to study the logic, the method and the philosophy of science as well as those of the various special sciences, including the social sciences. The current number of the *Journal* (15, No. 59; November 1964) begins with three logical articles on the confirmation paradoxes by William M. Baumer, P. R. Wilson and Judith Schoenberg, respectively. An important section, "A New Approach to the Theory of Fundamental Processes", is by Mendel Sachs, of Boston University. It is remarkable how often to-day statements can be found in Mach's *The Science of Mechanics* which make good starting-points for modern physical theories. In a new attempt towards a unified theory in physics, Sachs quotes Mach: "However well fitted atomic theories may be to reproduce certain groups of facts, the physical inquirer who has laid to heart Newton's rules will only admit those theories as provisional helps, and will strive to attain, in a more natural way, a satisfactory substitute". The essential point of departure of the new approach is in the introduction of the following fundamental postulate: "The laws of Nature must be described in terms of field variables that may be associated only with elementary interactions". Sachs applies his theory to an interpretation of the Dirac field, the production and annihilation of particle-antiparticle pairs, Pauli's exclusion principle, electron spin, the Lamb shift in the spectrum of hydrogen and the hydrogen equation which has an additional term—a fundamental length. The new approach introduces the elementary interaction instead of the elementary particle as the fundamental entity of Nature. The three manifestations of elementary interactions in terms of the gravitational (Einstein), electromagnetic (Maxwell) and matter (Dirac) field descriptions can all be represented in terms of fundamental spinor and quaternion field variables. The quantitative predictions which result from this method are being studied at present.

## The British Association of Industrial Editors, Ltd.

THE periodic 'house magazine' is such an important instrument of communication between management and staff in our large industrial organizations to-day, and its appeal and popularity have become so firmly established, not only in the firms concerned but, by virtue of a wider circulation, in the minds of a larger public, both in the United Kingdom and overseas, that it is not surprising that there now exists an association of people primarily concerned with these industrial publications and with the

cussed "Structure and Functions of Prokaryotic Cells", Dr. A. Virtanen (Finland), who discussed "Milk Production without Proteins", and Dr. S. Ochoa (United States) on "Replication of Nucleic Acids in Viruses Containing R.N.A.". Of the remaining seventeen contributors—European, North American and South American—some dealt with plant endocrinology, the terminal oxidases of plants, acetyl co-enzyme A carboxylation reactions, and the implications of biological catalysis and of photosynthesis. There were three papers on neurophysiology, including one on the molecular aspects of curarization, two on antibiotics and three on experimental or population genetics. The session ended with rather a mixed collection of papers on human endocrinology, inflammation, the role of magnesium in mammalian life, and a new technique in electron microscopy.

Varied as the subjects were, there was no doubt, judging from the discussion and comments, that all of them in one way or another were of immediate interest both to the guests and to the Spanish biologists who were present.

The programme of the colloquium on the "Contributions of Ecological and Agricultural Research in the World Fight against Hunger" was made up of six sessions and a total of thirty-nine contributions. Spanish speakers predominated, but there were others from most Continental countries, Great Britain and America. A wide range of topics was discussed. Some were concerned with the broad principles of world production, others related to more specific problems of the Mediterranean region.

On a world basis, the importance of a more detailed knowledge of climatic conditions and vegetational, ecological and soil types was stressed, while the value of accurate maps for evaluation and comparison of the potential productivity of different regions was emphasized.

Another aspect was the place and role of food production in the national economy of developed and developing countries. For example, in many parts of the world water is the major factor limiting agricultural production, and careful consideration must be given to determining the best means of sharing the limited supplies between industrial, domestic and agricultural needs. Besides discussion of the water factor, there were papers concerned with the ultimate limits of productivity, nitrogen fixation and the most effective uses of fertilizers

and of the ever-increasing range of chemicals used in both agriculture and forestry.

In the colloquium on the "Physical Chemistry of Processes on Solid Surfaces" twenty-four papers were presented. The first, by P. J. W. Debye, on surface determination by X-ray scattering, set a high standard which was well maintained. The contributions ranged over the whole field of the relationship between surface structure and catalysis, including the use of radioisotopes in the examination of surface phenomena. Among those present were many of the leading authorities, and this ensured an unusually penetrating discussion of the many new ideas put forward. The colloquium, indeed, was an outstanding success, and it is good to know that the papers and discussions will be published in full.

The proceedings closed with a banquet on October 24 at which speeches of thanks and congratulations were made by visitors from Great Britain, Germany, Argentina and France. Reply was made by the Minister of National Education, Dr. Lora Tomayo, who presided at the banquet, and who was, until a few years ago, professor of organic chemistry in the Consejo's laboratories. His appointment as Minister was, indeed, a most interesting and welcome sign of the times, and an earnest of Spain's determination to put her scientific and technological development in the forefront of her programme.

Besides the banquet there was a full social programme which enabled visitors to meet one another and their Spanish colleagues and hosts under most agreeable conditions, and on the Sunday after the meetings an excursion was arranged to the Valle de los Caídos and the Escorial. All arrangements were excellently made, and our Spanish hosts were most generous.

Visitors were left with an impression of a great Spanish achievement. Not only has the Consejo firmly established itself over a wide field of learning and research, but also present plans envisage a rapid growth, particularly in buildings and facilities. At present, in many laboratories, the space available scarcely matches the excellence of the staff.

The work of the Consejo is likely to have a profound long-term influence on Spanish thought and organization. For this much of the credit must go to J. M. Albarceda. It is pleasant for us to reflect that he once spent two years in Britain as a Ramsay Memorial Fellow.

B. K. BLOUNT

## OBITUARIES

### Prof. J. M. Somerville

JACK MURIELLE SOMERVILLE, professor of physics in the University of New England, died suddenly on October 15, 1964. Though his silver hair made him look older, he was only fifty-one.

Born at Liverpool, New South Wales, in 1912 and educated at Wollongong High School and the University of Sydney, he began his career as a mathematician and on graduation won a Barker scholarship to Emmanuel College, Cambridge. When he returned to Australia in 1937, however, his main interest turned to physics and in 1938 he was appointed as one of the foundation members of the staff of the New England University College, where he was in charge of all teaching in both mathematics and physics. Thus began his long association with the present University of New England, an association interrupted for only four years during the Second World War when he returned to the University of Sydney as assistant director of radiophysics training in a war-time school to train operators and technicians in the then new science of radar. In 1954, when the College became autonomous as the University of New England, he was appointed as its foundation professor of physics and continued as head of the Department of Physics until his death.

Prof. Somerville's main research interests lay in the study of electric discharges in gases. His earlier work on discharges in magnetic fields earned him a D.Sc. from the University of Sydney in 1952, but he is chiefly known for his work on transient electric arcs and sparks which occupied the last fifteen years of his life. He liked to use a simple direct approach to physical problems whenever possible and developed a method for the study of spark channels, by which a current pulse, passing through the plasma of the channel, was made to leave an imprint on a thin insulating film covering the anode. From a study of these imprints the life history of a spark could be traced in detail over the first few microseconds of its existence. Later refinements of the work extended optical, spectroscopic and calorimetric methods to the study of these sparks.

Recognition of his work was wide and his circle of personal friends included many people working in related fields in the United Kingdom, Europe and America. He spent 1952–53 as Warren Research Fellow of the Royal Society at the University College of Swansea, and an extended trip in 1963 allowed him to visit many laboratories where work related to his interests was being carried on.

His influence on science in Australia was considerable and he was much sought after to serve on important committees both within and outside the University. He was a council member and past president of the Australian Institute of Nuclear Science and Engineering, a member of the committee at present drafting a new science syllabus for secondary schools in New South Wales and a member for many years of the Council of the University of New England.

Prof. Somerville's wise and kindly influence on his many students and colleagues will be long remembered, as will his contribution to the establishment of the University of New England.

N. H. FLETCHER

### Mr. C. C. L. Gregory

MR. GREGORY, who was killed in a street accident on November 24, 1964, will be remembered as the astronomer who set up the University of London Observatory at Mill Hill. However, he had many other interests and activities.

He was born on May 13, 1892, and developed an interest in astronomy in early life. He gained a B.A. honours degree at the University of Cambridge in 1915 and started research at the Imperial College of Science and Technology, London, where the Diploma of the Imperial College was conferred on him in 1917. From studying the ammonium spectrum in London, he went, in 1919, as chief assistant to the Helwan Observatory, Egypt, there

to make a major contribution to the photographic survey of nebulae with the 36-in. Reynolds reflector.

From 1921 he was lecturer in astronomy in the Mathematics Department of the University College, London. However, Mr. Gregory was a practically minded astronomer, and talk of a research observatory was soon opened between him and Prof. Filon. About 1924 a 24-in. reflecting telescope was found to be available. This was accepted from Mr. F. G. Wilson (County Westmeath) and erected in 1929 at Mill Hill. Mr. Gregory became the Wilson Observer. Under his direction the Observatory continued to expand—the large Radcliffe twin refractor was erected in 1939. He mixed day-time lecturing with Observatory management and night observing. He kept up a centre of undergraduate astronomical teaching in the University College at a time when other university observatories were turning preferentially to postgraduate studies.

Throughout his life he had a strong interest in parapsychology and metaphysics, and in 1950 he resigned from astronomy to turn completely to such subjects. In 1954 he was joint author with Anita Kohsen of a book entitled *Physical and Psychical Research (An Analysis of Belief)*. Later, Mr. Gregory and Miss Kohsen were married. Jointly they set up the Institute for the Study of Mental Images and brought out a journal entitled *Cosmos*. This journal was to terminate with its forty-first number, and by tragic coincidence Mr. Gregory's death occurred while No. 41 was being prepared.

C. W. ALLEN

## NEWS and VIEWS

### Biological Sciences in the College of Advanced Technology, Birmingham:

Prof. A. J. Matty

DR. A. J. MATTY, who is at present senior lecturer in comparative pharmacology in the University of St. Andrews, has been appointed professor of biological sciences and head of the new Department at the College of Advanced Technology, Birmingham, as from January 1. Dr. Matty, who is forty years old, was educated at the Central Grammar School, Birmingham, and at University College, Nottingham, where in 1948 he took a B.Sc. (Special) London External degree in zoology. In 1951 he obtained his Ph.D. at the University of Nottingham. Dr. Matty began his career as a demonstrator in zoology at the University of Nottingham, where he was later appointed lecturer. In 1959 he became lecturer at the University of St. Andrews, where, at the newly built Wellcome Laboratories of Pharmacology at the Gatty Marine Laboratory, he established teaching and research in comparative pharmacology. Dr. Matty's research has been concerned with comparative and cellular endocrinology, particularly on problems of thyroid function in lower animals. He was awarded one of the first Royal Society and Nuffield Foundation Commonwealth Bursaries in 1955 for research in Bermuda on the thyroid gland of *Scarus guamacia*. Other research work carried out by Dr. Matty has been concerned with the effect of thyroid hormones on membrane permeability, on the pituitaries of fishes, on cyclostome endocrinology, and on intestinal transport in mammals.

### Mathematics in the University of Keele:

Prof. A. P. Robertson

DR. A. P. ROBERTSON, whose appointment to the chair of mathematics in the University of Keele in succession to Prof. D. S. Jones was announced recently, was born in 1925. He pursued his undergraduate studies in the University of Glasgow, graduating M.A. with first-class honours in mathematics and natural philosophy early in 1946. Because of the requirements of the National

Service Act he was not able to leave Glasgow to continue his studies elsewhere and acted as an assistant lecturer in mathematics until October 1947, when he entered St. John's College, Cambridge, to read for the Mathematics Tripos. He gained a B.A. of the University of Cambridge in 1949 and Ph.D. in 1954 (being elected a Fellow of his own college in that year). Apart from a year in the University of Kansas, Dr. Robertson has been on the mathematics staff of the University of Glasgow since 1961, first as a lecturer and latterly as a senior lecturer. Dr. Robertson is well known for his original contributions to 'classical' analysis and functional analysis. This year saw the publication of the Cambridge Mathematical Tract *Topological Vector Spaces* written by Dr. Robertson and his wife; this has already been acclaimed as a most useful survey of an important part of functional analysis. His interest in reforms in the mathematical curriculum both at school and university, as well as his status as a research worker in an important branch of modern pure mathematics, fit him admirably for the chair he is now called to occupy.

### Physics in the University of Leeds: Prof. F. E. Hoare

DR. F. E. HOARE, reader in physics in the University of Leeds, has been appointed to an additional chair in the Department of Physics in the University. Dr. Hoare was educated at the Municipal Secondary School, Brighton, and the Imperial College of Science and Technology, London. He gained first-class honours in physics in the examinations for the degree of B.Sc. and Associateship of the Royal College of Science. He was awarded the degrees of M.Sc. in 1930 and Ph.D. in 1932 for work on radiation measurements. In 1928 Dr. Hoare was appointed assistant lecturer in physics at the then University College, Exeter, and was promoted to a lectureship in 1934. During the Second World War he was engaged on scientific work for the Admiralty. He joined the University of Leeds in 1946 as lecturer in physics and was promoted to a senior lectureship in 1952 and a readership in 1954.

interests of all those responsible for the increasingly high quality achieved in these productions. In *Communication* 64 (Pp. 56. London: The British Association of Industrial Editors, Ltd., 1964. 5s.), a review prepared by the British Association of Industrial Editors, there occurs this statement which clearly epitomizes the aims of this Association: "Communication can be the O.K. formula word, the fashionable word of industry, the vague, facile excuse word, the all-things-to-all-pseudos word. Properly considered it can be the key to understanding between individuals, groups and nations—the supreme aim of civilized society. Over a decade ago the President of the American Management Association said: 'The number one management problem to-day is communication'. The problem remains. This survey takes a realistic look at an ingredient vital to industrial and social progress". Among the articles in the present publication are "The Future of Mass Communications", by I. Colquhoun; "Men, Management and Morale in Efficient Business", wherein industrial relations and the importance of the systematic approach are reviewed by J. Garnett; "Walls between People", the eccentricities and idiosyncrasies which provide obstacles to communication, by G. C. B. Andrew; "The Meaning of B.A.I.E.", the growth of the Association from enthusiastic amateurs to professional status, detailed by G. Phillips; "British Editor: Industrial Species", a description of the present-day role of the industrial editor in Great Britain, by R. C. E. Dancer; "The Communicators"—being interviews with five leaders of industry on the role of communications; "Case Studies", some examples of success and failure in house journals analysed by E. H. Dodimead. This publication sets a standard not only in subject-matter and illustration, but also in style and presentation of the message it seeks to convey; if industrial editors responsible for house magazines, either established or at present only at planning stage, can emulate it, they will not go far wrong.

### Needs of the Scientific Writer

In a paper read at a Library Circle meeting of the Royal Institution in March 1964, and now published in the *Proceedings of the Institution* (No. 182, 40; 1964), Mr. J. G. Crowther describes with insight the dependence of the scientific writer on library facilities and the characteristics of the facilities such writers need. His warning that mere technical efficiency is insufficient is timely, but Mr. Crowther could well have mentioned also the need for an easy and rapid means of verifying references and quotations. Mr. Crowther refers appreciatively to the establishment of the National Lending Library for Science and Technology. His talk deserves attention from the Committee on Libraries of the University Grants Committee, as well as elsewhere, for it points to some gaps in the national library system which call for imaginative attention. The scientific writer has an important part to play in spreading a general understanding of science and technology and in raising productivity, and he cannot do so with full efficiency unless these library needs are met.

### New Zealand Forestry

THE annual report of the Director-General of Forests, New Zealand, for the year ended March 31, 1964, makes very interesting reading (Pp. 59. Wellington: Government Printer, 1964. 2s. 6d.). New Zealand's forest economy is largely dependent on her exotic coniferous forests, and now they have three times the output of the indigenous forests. More than this, the annual exports of forest products have risen in the past ten years from less than £1 million to nearly £11 million. This prosperity is to a great extent associated with the rapid rise of the pulp and paper industry, for more than three-quarters of the 1963 exports was due to newsprint and pulp. Indeed, it is significant that these two items accounted for nearly half New Zealand's exports to Australia, and forest products now rank high in a country which is traditionally

associated with agricultural produce only. There is plenty of land available for acquisition by the Forest Service, especially land that is marginal for agriculture. But some unsuitable land is being offered because would-be sellers too often look on forestry as a form of land use to take over where agriculture has failed. With the availability of land as it is, there is every likelihood that there will be an increased rate of planting by both State and companies, although private planting may have to be given incentives because during the past 30 years it has lost some of its public appeal as a commercial investment. The New Zealand Forest Service provides a vigilant timber inspection. Packing-cases are regarded as one of the most dangerous means of entry of forest insects into the country. There is the not unusual animal-control controversy, but the Forest Service insists that its policy is to enforce proper control and not to exterminate. Over-population of noxious wild animals on catchment areas can sometimes be associated with flooding. Forestry in New Zealand continues to prosper in a very convincing manner.

### Bibliography on British Soils

INFORMATION on soils is presented in such a large number of scientific journals and memoirs that it is often difficult for anyone not actually engaged in soil science investigations to decide where to look for appropriate reliable data. It was with this in view that *An Annotated Bibliography of Memoirs and Papers on the Soils of the British Isles*, by B. T. Bunting, was published in time for the twentieth International Geographical Congress (London) and the eighth International Congress of Soil Science (Bucharest) (Part 1: *The Classification, Morphology, Distribution and Reclamation of British Soils*. Pp. iv+100. London: Geomorphological Abstracts, Department of Geography, London School of Economics, 1964. 10s.). In the main, it includes papers dating from 1920. Authors and titles are given with occasional cross-references and, in many cases, an abstract is added. Part 1 of the *Bibliography* deals with classification, morphology, distribution and reclamation, and consists of two parts: the first is of 11 sections on systematic and general papers, the second is on regional and local papers for 16 regions. There is an author index. A second volume (Part 2) is planned to deal with the internal properties and external relationships of British soils.

### Odour in Theory and Practice

INCREASING specialization brings with it the advantage that every available scientific and technical approach can be brought to bear on a single problem. Odour is a case in point. Its practical importance is so great in so many ways that it is scarcely surprising to find numerous laboratories devoted solely or mainly to the investigation of various aspects of the chemistry, physiology, psychology, measurement, analysis, correlation, control and production of odours and fragrances. These topics are described in the report of a conference entitled *Recent Advances in Odor: Theory, Measurement, and Control* (*Annals of the New York Academy of Sciences*. Vol. 116, Article 2. By Richard L. Kuehner and 60 other authors. Pp. 357-746. New York: New York Academy of Sciences, 1964). What emerges from this comprehensive account is the complexity of the subject and the realization that perception of odour, particularly by a trained perfumer, often still exceeds the sensitivity of vapour phase chromatography. To someone who is not a specialist in the field of odour research, its ramifications come as a surprise. To begin with, atmospheric pollution, especially by particular industries, is a source of odour which was tolerated by local residents in the past but is now no longer acceptable. Odour control in the crowded urban environment, both outdoors and indoors, assumes equal importance with reduction of noise. Body odour and deodorants are a fertile field of research. The importance of odour or fragrance in market-

ing products (quite apart from cosmetics or toiletries) appears to extend to synthetic fertilizers and plastic records. Despite the wide scope of the conference, some important aspects of the subject, of particular relevance to food, were not touched on: for example, the relationship between odour and flavour or the nature, causes and prevention of taint. A method for characterizing odour qualities was developed in order to permit an accurate description of the odour of irradiated beef. Based on matching standard odours described as "oily, sweet, fragrant, spicy, burnt, rancid, metallic, etherish and sulphurous", it conjures up anything but an inviting gastronomic experience until one realizes that fresh meat, too, is accounted for in the same terms, but with rather less of the etherish and sulphurous elements.

### Low Temperature Biology Club

AN informal association of biologists, physicists, clinicians and surgeons interested in biological and medical effects of cold has recently been formed, to be known as the Low Temperature Biology Club. The next meeting will be held at Westminster Hospital, London, on March 22. Further information can be obtained from Dr. M. J. Ashwood-Smith, Medical Research Council Radiobiological Research Unit, Harwell, Didcot, Berkshire.

### Fulbright Travel Grants

UNDER the provisions of the Fulbright programme, travel grants are available to citizens of the United Kingdom and dependent territories to go to the United States of America for academic or educational purposes, provided that they have adequate financial support in dollars for the proposed period of the visit to the United States, and can show proof of admission to an institution of higher learning in the United States for a minimum period of nine months. All grants cover the cost of direct round-trip travel between a candidate's home and the American university or institution. They are available between June 1, 1965, and August 7, 1965, for which applications must be received before March 16, 1965, and between August 8, 1965, and April 1, 1966, for which applications must be received before June 1, 1965. Application forms and further information can be obtained from the United States Educational Commission in the United Kingdom, 71 South Audley Street, London, W.1.

### National Science Foundation Fellowships

NATIONAL Science Foundation fellowships, enabling the recipients to teach and conduct research at universities in the United States for 5-12 months, have been awarded to the following: Prof. F. A. Drahowzal, professor of chemistry at the Technical University of Vienna; Prof. F. R. Keogh, professor of mathematics at Royal Holloway College, University of London; Dr. T. Nakada, director of the Research Laboratory of Precision Machinery and Electronics at the Tokyo Institute of Technology; Prof. R. H. Stokes, professor of chemistry in the University of New England, New South Wales; Dr. P. J. Wheatley, senior research chemist with the Monsanto Research Laboratories, Switzerland.

### The Night Sky in February

NEW Moon occurs on Feb. 1d 17h U.T. and full Moon occurs on Feb. 16d 00h. The following conjunctions with the Moon occur: Feb. 3d 10h, Saturn  $4^{\circ}$  N; Feb. 9d 03h, Jupiter  $2^{\circ}$  N; Feb. 17d 22h, Mars  $1^{\circ}$  S. Mercury is in conjunction with the Sun on Feb. 24d 03h and Saturn on Feb. 26d 10h. Conditions continue to be unfavourable for observation of Mercury and Venus. Mars rises at 20h 50m, 19h 45m and 18h 15m on Feb. 1, 14, 28 respectively; its distance from the Earth on Feb. 14 is 69 million miles; its stellar magnitude is  $-0.7$  and it is in Virgo. Jupiter sets at 1h 50m, 00h 55m, 23h 55m at the beginning, middle and end of the month; its distance from the Earth on Feb. 14 is 469 million miles; its stellar magni-

tude is  $-1.9$  and it is in Aries. Saturn sets at 18h 50m, 18h 00m at the beginning and middle of the month, while towards the end of the month Saturn is too close to the Sun for observation, setting before sunset; its distance from the Earth on Feb. 14 is 995 million miles and it is in Aquarius. Occultation of the following star brighter than magnitude 6 occurs: Feb. 10d 19h 08.8 m, 129 H<sup>1</sup>. Tau (D). D refers to disappearance.

### Announcements

AIR COMMODORE SIR FRANK WHITTLE is to be the first recipient of the Goddard Award of the American Institute of Aeronautics and Astronautics, for his work in pioneering the gas turbine as a jet-propulsion aircraft engine.

THE American Physical Society Prize for 1964, sponsored by the Hughes Aircraft Company, has been awarded to Prof. Melvin Schwartz, professor of physics at Columbia University, in recognition of his experimental studies of weak interactions and in particular for the use of high-energy neutrinos.

THE first Edward B. Rosa Award of the National Bureau of Standards has been presented to Mr. I. H. Fullmer, in recognition of leadership in development and promulgation of screw-thread standards, and to Dr. A. T. McPherson, for significant educational and organizational achievements in standardization.

A SYMPOSIUM under the auspices of the Faraday Society on "Excess Functions in Molten Salts" will be held at the Imperial College of Science and Technology, London, on February 25. Further information can be obtained from Dr. E. Rhodes, Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, S.W.7.

A SEMINAR for science writers on "Quasi-stellar Radio Sources", sponsored by the American Institute of Physics and the National Association of Science Writers, Inc., will be held in New York City on January 26. Further information can be obtained from Mr. E. H. Kone, American Institute of Physics, 335 East 45th Street, New York 10017.

A MEETING of the Midlands Section of the Society for Analytical Chemistry will be held in the University of Birmingham on February 2. A paper entitled "pH and its Significance" will be presented by Prof. W. F. K. Wynne-Jones. Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

THE annual general meeting of the North of England Section of the Society for Analytical Chemistry will be held in Manchester on January 30. The retiring chairman's address entitled "Fat Extraction in the Analysis of Food-stuffs and Related Material" will be presented by Mr. C. J. House. Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

THE following educational and training courses will be held at the Production Engineering Research Association of Great Britain during 1965: *five-day courses*, general appreciation; practical machining and metal cutting; modern machining techniques; pressworking techniques; toolroom techniques; senior apprentice, parts 1 and 2; *two-day courses*, tool grinding; machine installation and maintenance; machine alignment and performance tests; production inspection; quality control. Further information can be obtained from the Information Manager, Production Engineering Research Association of Great Britain, Melton Mowbray, Leicestershire.

CORRIGENDUM. It is regretted that the telephone number of Cahn Instrument Co., Ltd., 27 Essex Road, Dartford, Kent, appeared incorrectly in the January 9 issue of *Nature* (205, 1; 1965). It should read Dartford 21540.

## ADVISORY COUNCIL ON SCIENTIFIC POLICY

APPENDED to the seventeenth annual report of the Advisory Council on Scientific Policy\* are the usual tables to be found in recent reports giving details of support of research at universities and colleges of advanced technology by the Research Councils, Government expenditure on civil research, and an analysis of the expenditure and staff of the Research Councils. Figures are also appended for science and mathematics graduate teachers in grant-aided schools and establishments, for first degrees and diplomas awarded in science and technology in 1962-63 and new membership of scientific and technological professional institutions. In view of tendentious questions asked in Parliament, the Advisory Council has also done well to append the memorandum of advice regarding a World Health Research Centre sent to the Minister for Science in February 1964. In addition to topics discussed elsewhere (see p. 319 of this issue), the main report also refers briefly to the International Biological Programme proposed by the International Council of Scientific Unions, and to the position of research in oceanography and marine biology, particularly in the laboratories of the Fisheries Department.

Expenditure by the Research Councils in support of research at universities and colleges of advanced technology is estimated at £12.1 million in 1963-64 and £14.8 million in 1964-65, compared with expenditure from the Exchequer grant to universities through the University Grants Committee of £31 million and £37.1

million, respectively. Of the £12.1 million, £5.2 million was on research grants, £2.5 million on research units within universities and colleges of technology, and £1.6 million on research units associated with them; and £2.4 million on postgraduate studentships and fellowships: for 1964-65 the corresponding figures are estimated as £6.8 million, £2.7 million, £1.57 million, and £2.8 million, respectively. Government expenditure on civil research is estimated at £174 million in 1963-64 and £204.5 million in 1964-65; of these totals, £14.1 million and £15.8 million, respectively, are on agriculture, forestry, fisheries and food; £41.5 million and £49.7 million, respectively, on industry and communications; £7.7 million and £9.7 million on medicine and health; £2.3 million and £2.28 million on overseas research; £52.8 million and £56.9 million on nuclear science; £31.2 million and £37.6 million on universities and learned societies; and £24.6 million and £32.5 million were spent in other ways, mainly through the Ministry of Aviation. Science and mathematics graduate teachers in grant-aided schools and establishments in England and Wales increased from 20,870 in 1962 to 22,121 in 1963; corresponding figures for Scotland being 5,255 and 5,338. In 1962-63, 7,728 first degrees and diplomas were awarded in science faculties and 3,983 in technology faculties, compared with 7,080 and 4,188 in 1961-62; 1,073 diplomas in technology were awarded in 1963-64, compared with 927 in 1962-63 and 620 in 1961-62. New membership of scientific and technological professional institutions increased from 11,057 in 1962 to 12,135 in 1963.

## BRITISH AID TO THE WEST INDIES

IN *Aid to the West Indies*\*, Mr. D. J. Morgan surveys attitudes and needs for the Overseas Development Institute seeking to elucidate obstacles to the effective use of British aid. An introductory chapter is followed by successive surveys of Bermuda and the Bahamas; Jamaica, Trinidad and Tobago; British Guiana; and Barbados, the Leeward and Windward Islands. Finally, some proposals are advanced for changes to maintain and increase the effectiveness of Britain's aid, including an immediate conference on the subject. The survey was assisted by a six-week visit to the West Indies during February-March 1964, in which problems of obtaining and using British aid were discussed.

Mr. Morgan found a general feeling in the West Indies that over the past decade or so interest has passed from their problems to those of Africa, and although bilateral aid from the United Kingdom to the West Indies has increased from £4.38 million in 1945-46 to 1956-57 to £14.95 million in 1960-63, in the same period the proportion going to the West Indies has fallen from 10 per cent to 7.45 per cent. Nevertheless, although no single development plan in the West Indies was wholly financed from Colonial Development and Welfare Funds in the late 1950's, four of the plans for 1960-64 were. Research assistance provided through the Department of Technical Co-operation is still predominantly for Africa and the West Indies, with the main emphasis in the fields of natural resources and medicine. Apart from the effect of price changes and, to a limited extent, the collapse of the

Federation, there is little evidence of neglect. However, Mr. Morgan suggests that the relatively high *per capita* income found side by side with high unemployment calls for special assistance. The grant-in-aid system appears to sap local initiative, while there are serious delays in aid administered through London as compared with American and United Nations programmes.

Accordingly, a regional aid office is suggested to administer Britain's contributions and regional programmes in agriculture, medicine, education, technical training and rural credit, and this should be a major item on the agenda for the proposed conference.

The main emphasis of the survey is on such regional schemes and programmes for medicine, agriculture, education, technical training, development banking, etc. While the people of the West Indies receive more aid from Britain than almost any other part of the Commonwealth—£8 million in 1962-63, an annual average of more than £3 a head for the past three years, apart from a substantial subsidy through the Commonwealth Sugar Agreement—more information about the programme in the area would probably make it more effective. Technical assistance to the West Indies in 1961 was £461,400, rising to £713,000 in 1963, compared with bilateral totals for all countries of £15.4 million and £24.3 million, respectively. Mr. Morgan suggests that these figures indicate a relative neglect of the West Indies in technical assistance.

The survey is the first of those from the Overseas Development Institute concerned primarily with the recipient and not the donor aspect of British aid. It lacks something of the clarity which has characterized earlier reports from this Institute.

## ELECTRICAL DOUBLE LAYER IN SURFACE AND COLLOID CHEMISTRY

AN informal discussion of the Faraday Society on the electrical double layer, particularly in relation to colloid and surface chemistry, was held in the New School of Chemistry of the University of Bristol during September 21-22. The meeting was attended by 129 people, 57 of whom came from industrial organizations and 72 from academic institutions. There were 22 visitors from overseas.

The chair for the session on September 21 was taken by Prof. D. H. Everett (University of Bristol). After a brief welcome to the visitors by Prof. Everett, Dr. R. Parsons (University of Bristol) opened the scientific sessions with a lecture which reviewed the history, and attempted to assess the importance, of the influence of the discrete nature of the charges on the structure of the electrical double layer. He distinguished the effects on the diffuse layer, originally suggested by Frumkin<sup>1</sup> and later developed by Stillinger<sup>2</sup> and Levich and Krylov<sup>3</sup>, from the effects on the compact part of the double layer, which can be traced back to de Boer<sup>4</sup> and which have been worked out in more detail by Esin and Shikov<sup>5</sup>, Ershler<sup>6</sup>, Grahame<sup>7</sup>, Levich<sup>8</sup>, Levine<sup>9</sup>, and Macdonald and Barlow<sup>10</sup>. The uncertainties which exist in these models, that is, the role of the solvent, the effectiveness of the imaging by the outer Helmholtz plane, etc., were mentioned. The importance of devising critical experiments to test these models was emphasized.

Drs. S. Levine (University of Manchester), J. Mingins (Unilever, Port Sunlight) and G. M. Bell (Chelsea College of Science and Technology) discussed, in terms of the discrete ion effect, a number of phenomena at charged interfaces which at present appear inconsistent with the classical Gouy-Chapman-Stern double-layer theory. These authors found that application of the discrete ion theory gave approximately constant values of specific adsorption energy with variation of surface charge, predicted a maximum in the potential at the outer Helmholtz plane with increase in primary charge at fixed ionic strength in the electrolyte, and explained the decrease in concentration of electrolyte required for flocculation of hydrophobic sols with increasing surface charge density. A satisfactory explanation could also be obtained for the phenomenon of mutual antagonism encountered in the flocculation of sols with mixed electrolytes.

The results of potentiometric investigations on the electrical double layer at the silver iodide crystal-solution interface were described by Prof. J. Lyklema (University of Wageningen, Netherlands). The double-layer properties of the silver iodide interface were compared with those of the mercury interface, and the differences and similarities discussed. Adsorption of cations on a negatively charged silver iodide interface was found to be considerably larger than on mercury, probably owing to specific effects. Evaluation of the ionic components of charge at a given potential showed that the adsorption of cations increased in the lyotropic order; a sequence which was also reflected in the flocculation values and in ion exchange. An interesting feature was that the negative adsorption of co-ions did not level off to a given value, as it does on mercury, but passed through a maximum.

Drs. J. J. C. Oomen and Prof. J. Th. G. Overbeek (University of Utrecht, The Netherlands) described measurements of the impedance of silver iodide electrodes, in aqueous solution over a range of  $pI$  and electrolyte concentrations, at frequencies in the range 120 c/s-6,000 c/s. The double-layer capacities of the silver iodide-solution interface obtained using this technique turned out to be very large and dependent on frequency. An

explanation was advanced in terms of surface roughness, and it was shown that on this basis the impedance of the electrode at low frequencies would reduce to a frequency independent series combination of a resistance and a capacity. Experimentally a linear dependence of the square root of the frequency was observed and the differential capacities extrapolated to zero frequency paralleled those obtained with silver iodide suspensions using the potentiometric technique. The ratios of the micro-area to the macro-area were found to be in the range 4-5.

The chairman for the second session, held on September 22, was Prof. J. Th. G. Overbeek. The session commenced with a theoretical paper by Dr. P. H. Wiersema (University of Utrecht, The Netherlands) on the relationship between the electrophoretic mobility and the zeta-potential of a spherical colloid particle. Earlier work on this problem by Overbeek<sup>11</sup> and Booth<sup>12</sup>, which had taken into account both electrophoretic retardation and the relaxation effect, had given approximate analytical expressions for mobility as an incomplete power series in terms of zeta-potential, with coefficients which were functions of  $\kappa a$ ;  $1/\kappa$  is the Debye-Hückel double-layer thickness and  $a$  the radius of the particle. The present work used a numerical solution which corresponds to the complete power series. The differences between the approximations and the present results were appreciable in the region of  $\kappa a$  between 0.2 and 50, and it appeared that the earlier treatments had over-estimated the relaxation effect.

Dr. R. H. Ottewill and Mr. J. N. Shaw (University of Bristol) described an experimental investigation on the electrophoresis of spherical colloidal particles in media of different ionic strengths. Polystyrene latex particles which had been prepared by means of an emulsion polymerization method were used for the investigations; the charge of the particles originated from carboxyl groups on the surface. Five monodisperse preparations were examined with diameters ranging from 600 Å to 4230 Å. Electrophoretic measurements were made using both moving boundary and ultramicroscopic electrophoresis in a range of concentrations of 1:1, 1:2 and 1:3 electrolytes. When examined as a function of  $\kappa a$ , the experimental mobilities gave curves which were qualitatively of the form predicted theoretically by Overbeek<sup>11</sup>, Booth<sup>12</sup> and Wiersema<sup>13</sup>. However, even using the more complete treatment of Wiersema some difficulties were experienced in evaluating zeta-potentials for particles of high mobility with  $\kappa a$  values in the range of 1-10.

Simultaneous measurements of the thickness and conductivity of isolated black foam films were reported by Drs. J. S. Clunie, J. M. Corkill, J. F. Goodman and C. P. Ogden (Procter and Gamble, Ltd., Newcastle upon Tyne). Films having the shape of open rectangular prisms were drawn from solutions of decyltrimethylammonium decyl sulphate, containing sodium bromide (varied from 0.0005 to 0.5 M), and 3-(dimethyl hexadecylammonio)-propane-1-sulphonate, containing sodium bromide (varied from 0.0005 to 1.0 M). The conductance of each film was measured parallel to the surfaces using bright platinum rectangular electrodes and a screened a.c.-bridge. At the limiting film thickness the conductivity measurements indicated an apparent excess of electrolyte in the film core as compared with the bulk solution from which the films were drawn. An explanation of the experimental data was given in terms of Bikerman's theory of surface conductance<sup>14</sup>, and application of Bikerman's equations led to a zeta-potential of about 50 mV for the surface layer/film core interfaces in both systems.

Drs. B. A. Pethica, M. M. Standish, J. Mingins and D. H. Iles (Unilever, Port Sunlight) introduced prelimi-

nary results designed to test the various assumptions made in the thermodynamic theory of the Volta effect. The critical analysis of these assumptions given by Koenig<sup>15</sup> was closely followed. The results were obtained using a vibrating plate electrometer and depended on measuring the compensation potential at the air/electrolyte solution interface in the presence and absence of various spread monolayers. The variation with applied field of the true surface potential ( $\Delta\chi$ ) for some phospholipid monolayers in the zwitterionic form was shown to cast doubt on the general validity of the Bridgman assumption. Within experimental error, the compensation potential does not vary with the separation of the vibrating plate and the solution surface. The Lorentz-Kelvin and Kelvin assumptions though not directly disproved can only be fortuitously correct in particular cases. Tentative proposals for the orientation of water molecules at the solution surface were made.

## NEW BRITISH ANTARCTIC BASE

A SMALL scientific exploration team from the British Antarctic Survey base at Halley Bay has established a research base in unexplored territory 170 miles south of Halley Bay and about 800 miles from the South Pole.

Sir Vivian Fuchs, director of the British Antarctic Survey, who led the Transantarctic Expedition in 1955, stated recently in London that: "This journey into entirely new territory has not only made possible a valuable contribution to ionospheric studies, but has paved the way for a future journey to link up our mapping programme with the work done further south by the Transantarctic Expedition".

The six-man team, led by Dr. G. Bowra, field leader, and Mr. W. Bellchambers, chief scientist, have established themselves at 77° 57' S., 24° 48' W., and have set up an ionosonde to measure the height and density of electrons in the ionosphere between 60 and 250 miles above the surface. Their main object will be to measure the drift of electron clouds over the Antarctic.

The new station, which will be a summer base, was reached after a difficult and hazardous 13-day journey over the ice field in two snow tractors, towing sledges. One of the sledges carried a 'caboose' housing scientific equipment. The equipment is powered by light-weight Villiers 'Mini-Gen' generators, giving about 1 kW of power.

Mr. Bellchambers heads a team of young scientists, mainly from the University College of Aberystwyth, who

are spending two years in Antarctica as part of the British contribution to international research during 1964-65 (designated International Years of the Quiet Sun).

The area in which the British team is working is of particular scientific interest because it is at a very high geographic latitude (so that the Sun does not set for several months in the Antarctic summer) but at a low magnetic latitude. This means that the relation between the ionosphere, the magnetic perturbations, the aurora and the meteorology of the high atmosphere are relatively simple. Such extreme relations between these factors are not found elsewhere in the world.

The Halley Bay equipment for studying the ionosphere includes ionospheric absorption measuring equipment belonging to the Department of Scientific and Industrial Research, an ionosonde and other equipment, some of which is used in co-operation with the United States base at the South Pole.

The team which established the new base consists of: Dr. G. Bowra, field leader and medical officer, Springfield, Ashted Park, Ashted, Surrey; Mr. W. Bellchambers, senior scientist, 40 Hilltop Road, Whyteleafe, Surrey; Mr. L. Dicken, physicist, Dunedin, 18 Risca Road, Rogerston, Newport, Mon.; Mr. P. C. Goodwin, meteorologist, Haughton House, Humshaugh, Hexham, Northumberland; Mr. G. A. Thompson, tractor driver-mechanic, Hope House Cottage, Ettrick, Selkirkshire, Scotland; Mr. B. Kraehenbuehl, Angaston, South Australia.

## GEOLOGICAL EXPEDITION TO CAPES DYER AND SEARLE, BAFFIN ISLAND, CANADA

By PROF. J. TUZO WILSON, O.B.E.\*, and D. B. CLARKE

Institute of Earth Sciences and Department of Geological Sciences, University of Toronto

THE occurrence of Upper Cretaceous and early Tertiary lava flows and sedimentary beds on the Atlantic coasts of Scotland, East and West Greenland, and of similar, but younger, rocks on intervening islands led to the expectation that such rocks might be found in North America<sup>1</sup>. Small patches of Tertiary sedimentary rocks have long been known on the coasts of Ellesmere Island and Northern Baffin Island<sup>2</sup>. In 1952, flat-lying

lavas of undetermined age were photographed at Capo Searle at latitude 67° 12' north on the east coast of Baffin Island<sup>3</sup>. They were later briefly described<sup>4</sup>.

This discovery has special significance in view of A. Wegener's hypothesis<sup>5</sup> that Greenland and northern Canada were separated by the spread of Baffin Bay accompanied by transcurrent faulting along the straits between Ellesmere Island and northern Greenland, and J. T. Wilson's corollary suggestion<sup>6</sup> that a branch of the

\* Present address: Churchill College, Cambridge.

North Atlantic Ridge should extend up the centre of Baffin Bay. If this is true, then the volcanic rocks at Cape Searle should once have been in contact with the extensive areas of Upper Cretaceous and early Tertiary sedimentary and volcanic rocks which have been described by S. Munck and A. Noe-Nygaard<sup>7</sup> and others on the west coast of Greenland in the vicinity of Disco Island.

Examination of air photographs by D. B. Clarke, a graduate student, revealed about 20 separate patches of lava along the 55 miles of coast between Cape Searle and Cape Dyer. None appeared to be more than 1 square mile in area, and all were close to the sea.

On July 14 a field party, supported by a grant from the Department of Northern Affairs and National Resources, Canada, flew to Baffin Island with the object of searching for fossiliferous strata, mapping the stratigraphy and geological structures of the coastline, and collecting oriented samples of the lavas for palaeomagnetic examination and isotopic age determinations.

After spending a week examining on foot the lavas on top of cliffs at Cape Dyer, the party flew to Broughton Island, 30 miles north of Cape Searle, and travelled south along the coast in Eskimo whaleboats. One of us (J. T. W.) returned on August 1, but D. B. Clarke, assisted by J. Dodds, spent two months in the field.

The coastline consists of a series of high, exposed head-lands separated by deep fiords and valleys. The flat-lying lavas were poured out on an earlier, irregular surface. Their contact with underlying Precambrian gneisses ranges from below sea-level to 1,700 ft. above sea-level, the average elevation being 1,300 ft., but at Cape Searle and on Padloping Island, where the lavas reach sea-level, several large normal faults were observed to strike parallel to the coast. Along them, either the coastal margin has been downfaulted or the interior uplifted. The outcrops of lava are up to 1,400 ft. thick and characteristically form prominent, vertical, seaward-facing cliffs. Single flows are usually about 10 ft. thick, but a few are as much as 150 ft. Zeolites were observed in many of them. Some flows were seen to terminate

abruptly, and correlation of sections between different outcrops is not easy.

No dykes were seen cutting Precambrian rocks, and those few observed in the lavas were very fine-grained with strikes roughly parallel to the coastline and nearly vertical dips.

In several localities, the base of the lavas rests on or is interbedded with sedimentary rocks up to 500 ft. thick. In some places, these sandstones, shales and conglomerates contain many fossil plants.

Dr. W. A. Bell, formerly director, Geological Survey of Canada, has made a quick, preliminary examination of a small sample of the material collected. His tentative conclusion, which he has allowed us to quote, is as follows: "The assemblage is all too meagre for reliable conclusion as to age other than a horizon within confines of Upper Cretaceous-Eocene inclusive. I do favour somewhat greater probability of a Palaeocene than of a late Upper Cretaceous or other ages".

This winter it is hoped that the full collection of fossil material can be examined and described. Petrographic investigations, potassium-argon age determinations and a comparison of the geological succession with those in West Greenland will be undertaken. It is hoped to continue field work next summer.

Except for a short period in August, field work was made difficult by heavy snow on the upland and sea ice obstructing passage around the head-lands or across bays.

We thank those who supported and assisted the expedition, especially Mr. John Macdonald, Hudson's Bay Co., Broughton Island, and the Eskimo boat crews under Pauloosie.

## POTASSIUM-ARGON AGE DETERMINATIONS FROM THE LEWISIAN OF GAIRLOCH, ROSS-SHIRE, SCOTLAND

By DR. C. R. EVANS\*

Geological Age and Isotope Research Group, Department of Geology, University of Oxford

AND

DR. R. G. PARK

Department of Geology, University of Keele

RECENT geochronological work on the Lewisian of the Scottish mainland from Assynt to Durness<sup>1-5</sup> has firmly established the ages of four major events—the Scourian metamorphism<sup>6</sup> (about 2,600+ m.y.), the Inverian metamorphism<sup>2,3</sup> (about 2,200 m.y.), the intrusion of a series of basic dykes (2,200 m.y.) and the Laxfordian metamorphism<sup>6</sup> (1,600–1,500 m.y.).

The later Lewisian ages obtained in this northern area show a marked spread. Giletti, Moorbath and Lambert<sup>1</sup> base their estimation of the date of the Laxfordian metamorphism mainly on two pegmatites, one in South Harris and the second, cutting a dyke in Scourian rocks, in Scourie, which give muscovite and feldspar ages in the range 1,650–1,550 m.y. In contrast, the gneisses and pegmatites of the 'type' Laxfordian area from Laxford to Durness give ages ranging from 1,530 to 1,280 m.y.

\* Present address: Imperial Oil, Ltd., 500 Sixth Avenue Southwest, Calgary, Alberta, Canada.

with a mean of 1,430 m.y. These younger Lewisian ages were considered to be due to mild reconstitution of Laxfordian (1,600–1,500 m.y.) rocks occurring later than about 1,100 m.y. and possibly of Caledonian age. The possibility that the Laxfordian metamorphism continued throughout the period represented by the spread in determined 'Laxfordian' ages was rejected, but the alternative possibility, that two separate metamorphic events are represented, was not considered.

Four samples from the Gairloch area were dated in this preliminary attempt to correlate its structural history<sup>7</sup> with that of the Lewisian to the north.

The geochronology of the Lewisian south of Assynt is relatively poorly known. One date is available for gneiss at Gruinard Hill, north of Gairloch (1,510 m.y.), two for muscovite-schist at Letterewe on Loch Maree, just east of Gairloch (1,510 and 1,540 m.y.), and two for gneisses at Loch Torridon, south of Gairloch (1,300 and

1,160 m.y.). According to the scheme proposed by Sutton and Watson<sup>6</sup> the first of the Loch Torridon samples is Scourian (presumably modified in the Laxfordian) and the remaining samples are Laxfordian, modified in the case of the Loch Torridon samples by reheating after 1,100 m.y., probably during a period of crushing<sup>1</sup>. The identification by Sutton and Watson of Scourian gneisses at Loch Torridon, and the supposition that the remaining gneisses of the southern Lewisian were originally also Scourian but have been reconstituted during the Laxfordian, thus find neither confirmation nor contradiction in the age determinations as yet, and depend on the correlation of basic dykes and sheets in this area with the Scourie dyke swarm of the north.

A detailed sequence of events, based on structural evidence, recently proposed by Park<sup>7</sup> for the Gairloch area differs from the Sutton and Watson chronology in several respects. A fragment of a presumed basement complex (the Ialltaig gneisses) metamorphosed in granulite facies is recognized. The surrounding rocks, considered to be later sediments, together with the Ialltaig rocks, are affected by three later tectonic episodes (early, main and late phases). Certain dykes which Sutton and Watson correlate with the 2,200 m.y. Scourie dykes here post-date the foliation of the main phase and are affected by the late phase. Both phases were accompanied by metamorphism, but it is not yet known whether two quite separate episodes occurred, separated by dyke intrusion, or whether metamorphism continued during the period of dyke intrusion as has been suggested for dykes in Scourie<sup>8</sup> and Assynt<sup>9</sup>. The metasomatism shown by the gneisses also post-dates the main phase, but again it is not known whether or not the two episodes are part of a continuous process. It is probable that metamorphism also accompanied the early phase, but any mineralogical effects of this episode are likely to have been swamped by the pervasive main-phase metamorphism.

GA 150/6 from the Ialltaig gneisses is a garnet-clinopyroxene-hornblende-plagioclase rock, with granulitic texture. Hornblende, the only mineral bearing significant amounts of potassium, is present in two varieties. The dominant variety is strongly pleochroic with the scheme X-pale yellow, Y-grass-green, Z-brown. It is partly replaced by a less pleochroic yellow-green to bluish-green variety. Both kinds partially replace pyroxene. The retrogressive alteration from granulite facies to epidote-amphibolite-facies can be correlated on structural grounds with the main phase<sup>7</sup>. The blue-green hornblende appears to be the typical main-phase variety, but the date of origin of the older brown variety is uncertain.

GA 39/3 from a basic sheet in the schists is a hornblende-oligoclase-quartz-schist, very fine grained, with extremely well-developed foliation caused by planar alignment of hornblende and by feldspar-hornblende banding. Quartz is a minor constituent. The potassium is effectively concentrated in the hornblende which is an actinolitic variety, pleochroic according to the scheme X-very pale yellow, Y-yellow-green, Z-bluish green. The foliation and the hornblende can be correlated with the main phase.

GA 114/8 from a thin basic sheet in the gneisses is a hornblende-oligoclase-epidote-quartz-amphibolite, with poorly-developed foliation caused by planar alignment of hornblende. Quartz and epidote are present in relatively minor proportions. Again, the potassium can be assumed to be concentrated in the hornblende, which has strong pleochroism (X-pale yellow, Y-deep yellow-green, Z-blue-green). The foliation of the sample originated in the main phase, but the surrounding gneisses have been affected by later metasomatism which presumably also caused some modification in the amphibolite.

GA 153/7 from a metamorphosed post-main-phase basic dyke is a hornblende-plagioclase-epidote-quartz-amphibolite. The hornblende and the plagioclase-epidote occur in aggregates pseudomorphing the original igneous crystal pattern of rather coarse grain. A few

altered biotite laths occur streaked with opaque brown material (probably iron ore) and associated with magnetite and sphene. The hornblende is moderately pleochroic (X-pale greenish-yellow, Y-yellow-green, Z-blue-green) and forms complex intergrowth patterns. The epidote-amphibolite-facies recrystallization of the sample is assigned to the late phase. The hornblende and the alteration of the biotite thus date from this episode.

The determinations of potassium and argon were carried out on whole-rock samples (120 mesh). Potassium was determined with a flame photometer using an addition dilution method<sup>2</sup>. Argon was extracted by fusing a weighed sample under high vacuum in a Mo crucible with a radio frequency induction heater, and was measured by standard isotope dilution techniques on a Renolds-type mass spectrometer. The decay constants used were  $\lambda_e = 0.584 \times 10^{-10} \text{ yr}^{-1}$  and  $\lambda_\beta = 4.72 \times 10^{-10} \text{ yr}^{-1}$ .

The results of this preliminary investigation (Table 1) indicate: (1) that one phase of recrystallization of the Ialltaig granulites can be attributed to a metamorphic episode between 1,600 and 1,500 m.y. which agrees with the three previous Rb-Sr dates from north of Gairloch and with the date of the 'type' Laxfordian of Laxford; (2) that at least one post-1,600 m.y. thermal event affected the Gairloch area. The 1,400 m.y. age is in good agreement with rubidium-strontium determinations on Laxfordian gneiss from Laxford and with gneiss and pegmatites from the Hebrides, and adds to the growing body of evidence indicating a distinct and widespread thermal event younger than the Laxfordian *sensu stricto*, but distinct from, and much older than, the reheating episode of Giletti *et al.*<sup>1</sup>. This event may correspond to the late phase of metamorphism in Gairloch.

Table 1. WHOLE-ROCK POTASSIUM-ARGON AGES OF ROCKS FROM GAIRLOCH

Sample No.	Description	<sup>40</sup> Ar rad. s.o.c./g $\times 10^{-4}$	% <sup>40</sup> Ar rad.	K, 0%	Age m.y.
GA 150/6	Garnet-pyroxene-hornblende-granulite	0.2154	92.4	0.275	1,530 $\pm$ 60
GA 39/3	Hornblende-schist	0.1785	89.2	0.258	1,400 $\pm$ 60
GA 114/8	Amphibolite	0.8079	95.9	1.389	1,240 $\pm$ 50
GA 153/7	Metamorphosed dyke	0.2739	92.4	0.538	1,120 $\pm$ 45

Location of samples:

GA 150/6: From the Ialltaig granulitic gneisses<sup>1</sup> of Ard Ialltaig, Loch Gairloch, locality NG 805736.

GA 39/3: From the Aundray basite<sup>2</sup>, one of a group of basic sheets associated with the Gairloch metasedimentary schists, locality NG 850720.

GA 114/8: From one of a group of amphibolite sheets in the Buainchean gneisses<sup>3</sup> of Gairloch, locality NG 861730.

GA 153/7: From one of the metamorphosed basic dykes forming the South Sithean Mor dyke complex<sup>4</sup>, locality NG 813716.

See Park<sup>7</sup>: (1) 401 and Plate 34; (2) 404 and Fig. 2; (3) 399 and Fig. 2; (4) 405 and Plate 34.

The two younger ages, however, may represent argon loss during a mild reheating at or later than 1,120 m.y. It may be significant that this date is close to the minimum age for this part of the Lewisian by Rb-Sr (1,160 m.y.).

The tentative dates of the metamorphic episodes in Gairloch are summarized in Table 2. Until further age-determinations are available it is not possible to correlate definitely the events at Gairloch with those of the northern Lewisian.

Table 2. TENTATIVE CHRONOLOGY OF METAMORPHIC EPISODES AT GAIRLOCH

1. Ialltaig metamorphism:	Certainly older than 1,530 m.y. Possibly = Scourian (2,600+ m.y.).
2. Gairloch early-phase metamorphism:	Certainly older than 1,400 m.y. Possibly about 1,530 m.y. (also = muscovite dates from Loch Maree) Possibly 2,200 m.y. (Inverian)
3. Gairloch main-phase metamorphism:	Certainly at least 1,400 m.y. Possibly = 1,530 m.y. (but could be much older).
4. Intrusion of South Sithean Mor dykes:	Certainly older than 1,120 m.y. Possibly younger than 1,530 m.y. (but could be older if (3) is older).
5. Gairloch late-phase metamorphism:	Certainly at least 1,120 m.y. Possibly younger than 1,240 m.y. (but could be older if (6) occurred).
6. ? Reheating episode:	Younger than 1,120 m.y. (alternative explanation of younger ages postulated by Giletti <i>et al.</i> <sup>1</sup> ).

We thank Prof. L. R. Wager and members of the Geological Age and Isotope Research Group at Oxford for making equipment available for the age determinations. We also thank Mr. D. C. Rex for performing the analyses.

## POTASSIUM-ARGON AGE MEASUREMENTS ON TWO IGNEOUS ROCKS FROM THE ORDOVICIAN SYSTEM OF SCOTLAND

By P. M. HARRIS\*, E. FARRAR, R. M. MacINTYRE and PROF. DEREK YORK

Geophysics Laboratory, University of Toronto

AND

J. A. MILLER

Department of Geodesy and Geophysics, Cambridge

THE time of occurrence of the Ordovician system<sup>1-3</sup> is not precisely known, and it was the purpose of the investigation recorded here to provide additional reference points. Table 1 summarizes pertinent data obtained by other workers.

Table 1

Locality	Rock	Mineral	Method	Date (m.y.)	Ref.
Upper Caradocian Kinnekulle, Sweden	Bentonite	Sanidine	K—Ar	452	4
		Biotite	Rb—Sr	447	
Middle Ordovician, Tennessee	Bentonite	Zircon	<sup>238</sup> U	447 ± 10	5
Middle Ordovician, Alabama	Bentonite	Zircon	<sup>207</sup> Pb	455 420 447 477 481	3
		Biotite	K—Ar		
		Biotite	Rb—Sr		
Middle Ordovician, Quebec	Granite	Muscovite	K—Ar		
	Granite	Muscovite	K—Ar	481	6

When interpreting these results it should be noted that the zircons referred to gave discordant U—Pb ages and that the K—Ar age of biotite from the Alabama tuff is distinctly below the Rb—Sr age. The latter effect is probably the result of slight loss of argon from the biotite, possibly as the result of some later event.

In this work the ages of two igneous masses are reported. The Ballantrae complex in Ayrshire and the Bail Hill volcanics of Dumfriesshire have both been assigned to the Ordovician on geological grounds and both include suitable biotite-bearing formations.

**Ballantrae Igneous Complex.** The Ballantrae Igneous Complex is made up of spilitic lavas and agglomerates together with serpentines and other basic and acidic intrusives. It is unconformably overlain by a Lower Caradocian conglomerate containing pebbles derived from the igneous rocks. It has been described by Peach and Horne<sup>7</sup>, Balsillie<sup>8,9</sup>, Anderson<sup>10</sup>, Pringle<sup>11</sup> and others. A review of previous work is given by Bailey and McCallien<sup>12</sup>.

The serpentine occurs in association with spilitic lavas of Middle Arenig age, and a similar age has been proposed for the whole complex by Peach and Horne<sup>7</sup> and by Anderson<sup>10</sup>. Bailey and McCallien<sup>12</sup> suggest that the serpentine originated as a submarine lava which forms a single sheet interposed between a lower and upper lavas series of Arenig age. Although these interpretations have been questioned by Balsillie<sup>8,9</sup> and Pringle<sup>11</sup>, further evidence of the age is given by the fact that the whole complex, including the Middle Arenig sediments, is typical of the spilitic-radiolarite-serpentinite association ('Steinmann Trinity') occurring in geosyncline belts in many areas.

Within the serpentine outcrop are a series of small exposures of gabbro, some of which are deformed and others thermally metamorphosed but undeformed. These

are thought to be broadly contemporaneous with the serpentine and are most probably intrusives<sup>12</sup>.

Samples of the gabbro were collected from a small outcrop 1½ miles north of Colmonell (Ayrshire). The rock is fresh and undeformed, although a slight schlieren structure is present which probably indicates mild pressure after emplacement. Thin-section examination shows it to consist of plagioclase feldspar, hornblende, pyroxene and biotite.

In order to separate the biotite, approximately 1.0 kg of the gabbro was crushed to less than 72 mesh B.S. In view of the similar magnetic properties of the biotite and hornblende in the rock, it was not possible to use direct magnetic separation; instead, flotation was used. As a necessary preliminary to the flotation process, which is inhibited by very fine-grained material, the crushed product was scrubbed and the resulting slime removed by decantation. The clean sample was then conditioned for 0.5 min in a 1-kg flotation cell at pH 3.5, using an amine collector and an alcohol frother. Air was admitted to the cell for 2 min and a good concentrate of biotite was obtained from the froth. After washing and drying, the concentrate was finally cleaned on a Frantz magnetic separator. Microscopic examination of the concentrate confirmed that it consisted of biotite with impurity contamination of less than 1 per cent.

**Bail Hill Volcanics.** The Bail Hill lavas, agglomerates and minor intrusions represent the site of an Ordovician volcanic pile which has since been subjected to regional folding. They have been described in detail by Peach and Horne<sup>7</sup>, who concluded that the volcanics were erupted mainly during Arenig times, as Arenig cherts are found in contact with the lavas. Furthermore, they point out that some volcanics are interstratified with shales containing Glenkiln graptolites (L. Caradocian) and suggest the possibility of this age for some of the late outpourings. More recently, Mrs. V. A. Eyles<sup>11</sup> has shown them to be later than the associated Upper Glenkiln shales. However, Pringle<sup>11</sup> has assigned all the Bail Hill volcanics to a Glenkiln horizon.

Among the Bail Hill lavas lies a mica andesite, samples of which were collected from an exposure in Grain Burn on the western slopes of Bail Hill approximately half a mile north-east of Kirkconnel, Dumfriesshire. A description of the outcrop together with sections across it is given by Peach and Horne<sup>7</sup>.

In thin section the mica andesite, which is vesicular, is seen to consist essentially of large phenocrysts of biotite and feldspar approximately 0.5–1 mm in length set in a fine-grained ground-mass. The biotite is pleochroic dark green to light green and shows the usual birefringence and characteristically small 2V angle, while the ground-mass is made up of very fine biotite and feldspars, though the

\* Present address: Warren Spring Laboratory, Department of Scientific and Industrial Research, Stevenage, Herts.

fineness of grain makes precise identification difficult. Opaque minerals, probably iron oxides, are present to the extent of 5–10 per cent.

Preparation of pure concentrates of biotite was carried out using a Frantz magnetic separator.

Potassium-argon age determinations made using the isotope dilution technique and flame photometry have been carried out on the separated mica fractions in Oxford, Cambridge and Toronto. Results are shown in Table 2. The close agreement among the results obtained by the different workers in different laboratories indicates that experimental errors in the ages found are definitely less than  $\pm 5$  per cent.

Table 2. RESULTS OF K/Ar DATING

Sample	Grain	Lab.	$\lambda_p = 4.72 \cdot 10^{-10} \text{ yr}^{-1}$		$\lambda_a = 0.584 \cdot 10^{-10} \text{ yr}^{-1}$		$^{40}\text{Ar}$ p.p.m.	Apparent age (m.y.)

Mean age of Colmonell gabbro = 475 m.y.								

T, Toronto; C, Cambridge; O, Oxford.

In assessing the reliability of the ages it is important to consider the possibility of argon loss from the micas due to their subsequent geological history. Thus, the Colmonell biotites may have been modified by a pre-Caradocian metamorphism, but as this probably occurred immediately after emplacement it is unlikely to have significantly affected the present argon content. The

widespread Caledonian earth movements which occurred approximately 415 million years ago<sup>12</sup> could conceivably have caused some argon loss from both the Colmonell and Bail Hill micas. Also the Bail Hill micas, which are green in colour and have a low potassium content, have been affected by hydrothermal activity or by weathering, which again could result in some argon loss.

Should these or other less-obvious events have affected the argon content of the micas, then our data would give minimum ages for these rocks.

We conclude that our results give reasonable grounds for assigning minimum ages of 445 million years to the Lower Caradocian and 475 million years to the Arenig. These new measurements and our interpretation are consistent with the data in Table 1.

We thank F. J. Fitch for his advice. This work was supported in Toronto by grants from the National Research Council of Canada and the Geological Survey of Canada and in Cambridge by the Department of Scientific and Industrial Research.

## LATIN SQUARE AS A NETWORK MODEL OF RANDOM PACKING

By PROF. C. C. HARRIS

Henry Krumb School of Mines, Columbia University, New York

THE analytical description of fluid flow and retention in porous media has been inadequate because of the complexity of pore geometry, while physical models, such as bundles of capillary tubes, have been oversimplified<sup>1</sup>. Fatt<sup>2</sup> recognized the stochastic nature of the replacement of one fluid in a porous mass by another, and proposed as a model a network of tubes arranged randomly in a matrix, with radii conforming to a predetermined frequency distribution. While the number of tubes was limited to 200–400, a test sample may contain 40,000 pores; nevertheless, the results with the 400 tube network were considered not seriously in error despite the 1 per cent sample size. Later authors report somewhat larger models<sup>3</sup> with computer analysis<sup>3,4</sup>. Monte Carlo methods were used to evaluate the emptying–filling sequence; the procedure will be given later.

Two of the variables examined by Fatt were tube radius distribution, and the number of tube interconnexions in the network. The conclusions were that the capillary pressure curves were more sensitive to changes in tube radius distribution than to changes in network. For low dispersion all networks have similar capillary pressure curves, while high dispersion leads to different curves for each network. Only one entry–exit configuration was used, the wetting phase being considered to escape from the network as a film on the pore walls. Later workers introduced entrapment where an encroaching fluid cannot displace an occupying fluid if no pore flow path is available for its escape.

The object of the present investigation was to study the effect of the entry–exit configuration on the capillary

potential curve, if possible by somewhat simpler matrix models and pencil and paper methods than the post-Fatt computer procedures.

### Network Model

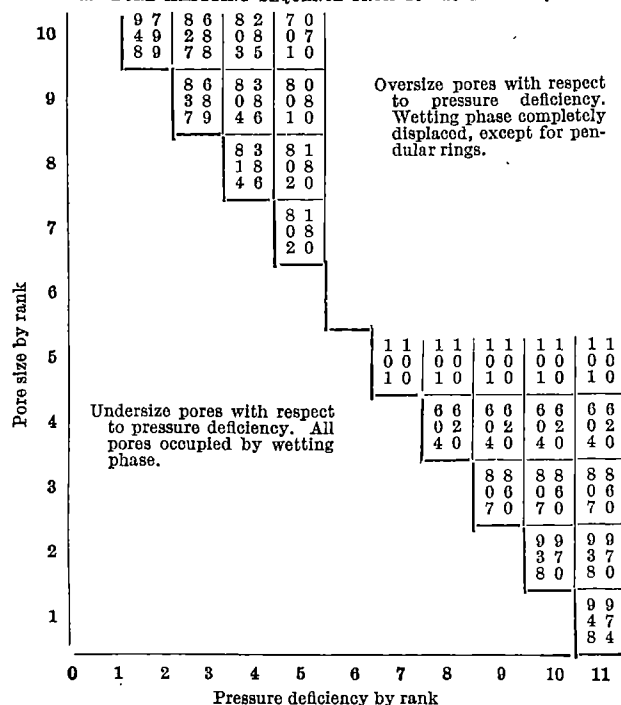

If any plane or any straight line is drawn through a random packing, the distribution of pore sizes so sectioned should be a representative sample of those in the packing. Consider the Latin square; the rows and columns (but not the diagonals) display these attributes in two dimensions accurately and with economy.

10 × 10 Latin squares were constructed by randomizing the columns and rows of a typical square<sup>5</sup>. Some selection was exercised, however, in rejecting squares having runs of successive integers, or of the same integer along diagonals.

*Procedure.* The imaginary apparatus and experimental procedure corresponded to the capillary potential experiment<sup>6</sup>. The square was completely occupied by the wetting phase (for example, water). A membrane which could conduct only the wetting phase (for example, a fine-pored sintered glass disk) was connected to certain edges, the remaining edges being connected to a reservoir containing the displacing phase (for example, air). Thus, as the wetting phase empties, the displacing phase takes its place. Increments of suction could be applied externally and conducted to the model through the membrane. The increments were graded by rank 1, 2, 3 . . . , so that pore size 10 could just empty by suction rank 2 (that is, pore 10 is oversize with respect to the applied suction rank 2), pore size 9 by suction rank 3, and so on. Each

Table 1. PORE EMPTYING SEQUENCE FROM 10×10 LATIN SQUARES

Average number of pores of stated rank still containing wetting phase after the application of stated pressure deficiency. The remaining pores contain pendular rings of wetting phase, and the displacing phase.

Key. Stepped line represents bundle-of-capillary-tubes model and divides the régime into oversize and undersize pores with respect to the applied pressure deficiency.

a	b
d	c
e	f

a, Displacing phase entering one edge. Wetting phase exiting from the opposite edge. b, Displacing phase entering three edges. Wetting phase exiting from one edge. c, Displacing phase entering one edge. Wetting phase exiting from three edges. d, Torus arrangement. Displacing phase entering about half the total number of pores. Wetting phase exiting from the remainder. e, Displacing phase entering two edges. Wetting phase exiting from two edges. f, Emptying sequence for fitting experimental data.

pore was connected to its eight neighbours, excepting the edge pores. Four connexions, along rows and columns, would appear more in keeping with the properties of the Latin square but not, however, with the complexity of a packing. An oversize pore will empty if both a complete wetting fluid path to the membrane and a complete displacing fluid path to the reservoir exist. Entrapment occurs when pores containing the occupying phase are surrounded by pores containing the displacing phase; edges and corners remote from the membrane are specially vulnerable. Other things being equal, with two pores of the same rank, the pore nearest the membrane was assumed to empty first, thus imposing a degree of selection on the model based on relative permeability concepts.

Having defined a set of rules, the ensuing desaturation sequences were obtained in the manner of a game (resembling, in some respects, the Japanese game 'Go'). The number of pores in the oversize ranks which still remained occupied after the effect from each increment of suction had proceeded to completion were counted; the results for various entry-exit arrangements are given in Table 1. The values shown are averages rounded to an integer, and here some judgment was exercised. Thus, considering oversize pores, it is possible that equal numbers of these will remain occupied (for example, pressure ranks 3 and 4, sequence (a) and (c)); however, on average it is not likely that more higher than lower rank pores will remain full. This criterion was used when rounding off.

The different arrangement (d) was designed to simulate a thin bed, the torus configuration being used to avoid edge effects. To deal with this apparently more difficult

case it is only necessary to repeat the left-hand column of the square on the right-hand side and the top row at the bottom, and vice versa to obtain cyclic continuity in both directions.

**Results.** Three conclusions may be drawn from Table 1. (1) At pressure deficiency rank 6 no oversize pores remain occupied by the wetting phase for all the different entry-exit arrangements investigated. All have at least this one point in common. (2) For pressure deficiencies below rank 6 the distribution of occupied oversize pores depends on the entry arrangement. The pattern is set at the 'entry pressure'; the curves merge towards the common point with no crossing over. (3) For pressure deficiencies higher than rank 6 entrapment occurs. The distribution of these occupied oversize pores depends on the exit arrangement; the curves diverge from the common point with no crossing over.

Thus, to single out just one factor for comment, the 'entry pressure' was dependent on the entry arrangement. Although interpretations of the present two-dimensional model in terms of a capillary potential experiment are uncertain, small thin samples would be expected to exhibit a somewhat lower entry pressure than thicker samples<sup>7</sup>.

The emptying sequence ceased when all the pores in contact with the membrane were empty. (In filtration the cake closest to the cloth is often the driest.) Had these remained full—that is, conducting—until otherwise unisolated pores elsewhere had emptied, a higher proportion of the wetting phase would have been withdrawn.

### Capillary Potential Curves

To display the emptying sequences of Table 1 as capillary potential curves, a pore-size frequency distribution will be considered and will be compared with the results of experiments on packings of equal spheres. This is strictly for purposes of illustration; it is not yet clear how to interpret such comparisons even if they are meaningful.

Fatt assumed cylindrical pores and reasoned that lengths were inversely proportional to radii; consequently

Fig. 1. Capillary potential curves derived from Latin square model

pore volume is proportional to radius. The pressure deficiency required to empty a pore was assumed inversely proportional to radius, in accordance with Laplace's equation (1) (Table 4). For the present purpose, Fatt's general relationships will be accepted, except that pore size (that is, radius) will here be interpreted as pore volume; there is no numerical difference on this account, only a change of scale because all Fatt's data were given in arbitrary units. A physical interpretation will be attempted by considering a packing of equal spheres (radius  $R$ ). Thus, scaled volume,  $\bar{V}_s = cV/R^3$  where  $V$  = pore volume and  $c$  is the scaling factor. Scaled pressure,  $\bar{P}_s$ , is a function of the dimensionless group  $PR/\gamma$ , where  $P$  is pressure deficiency, and  $\gamma$  is interfacial tension. Percentage frequency of pores of any specified size is  $f$ . Primary data similar to Fatt's first of three distributions (his Fig. 5) are given in Table 2; this is a moderately narrow distribution with slight positive skew. Considered as a bundle-of-capillary-tubes model, Table 2 leads to the capillary potential curve ( $g$ ) in Fig. 1.

To apply the desaturation sequences of Table 1, the primary data must be replaced with equivalent data expressed as a distribution of ten pore sizes of equal frequency. This is obtained by interpolation from a plot of  $\Sigma fV_s$  against  $\Sigma f$  at 10 per cent intervals giving equivalent scaled volumes,  $\bar{V}_s$ . The equivalent scaled pressure,  $\bar{P}_s$ , is best obtained from Fig. 1, curve ( $g$ ) interpolated from values of  $\bar{V}_s$  interpreted as a bundle-of-capillary-tubes model.  $\bar{V}_s$  and  $\bar{P}_s$  (Table 3) are consequently a set of data which can, when treated as a bundle-of-capillary-tubes model, generate substantially the same curve as the primary data.

**Pendular rings.** Fatt intentionally neglected all forms of residual wetting phase entrapment, while later authors<sup>3,4</sup> considered entrapment only in pores. The contribution of pendular rings to residual wetting phase saturation

has generally been neglected in network models. For equal spheres, the relationship between pendular ring volume,  $v$ , and the associated pressure deficiency has been tabulated<sup>5</sup>, while measurements indicate that the pressure deficiencies are substantially equal to the entry pressure for the pore<sup>6</sup>. Knowing the number of points of contact per sphere for the different regular packings, the saturation on account of pendular rings can be calculated (Table 4). (Theoretical pendular ring saturation cannot exceed 24.3 per cent for rhombohedral packing and 18.2 per cent for cubic packing<sup>8</sup>.)

With random packings of smooth equal hydrophilic spheres, the residual pendular ring saturation  $\Sigma v/\Sigma V \approx 4$  per cent. The remaining residual fluid  $\sim 3$  per cent is entrapped in pores, together with some possibly occurring as a non-conducting surface film.

The volume of pendular wetting phase associated with a pore depends on the throat radius, this in turn being related to the pore volume; the approximate relationships for the model assumed here are given by equations (2) and (3) and (6)–(8). However, because scaled values are being used, a linear relationship between pore and pendular ring volume will be assumed as a first approximation giving values intermediate between equations (6) and (7), and equation (8). Thus, the same scale ratio applies to both pendular rings and pore volume; that is:  $v_s/\bar{V}_s = v/V$ . A value of 4.2 per cent saturation for all pendular rings will be assumed, which is not unreasonable for packings of smooth rounded particles<sup>9</sup>.

**Theoretical curves.** The capillary potential curve derived from a bundle-of-capillary-tubes model with the addition of residual pendular rings is plotted in Fig. 1, curve ( $h$ ), and the sequences in Table 1 with pendular rings are shown as curves ( $a$ ) to ( $e$ ). Curve ( $b$ ) up to the common point is displaced about 2 per cent units to the left of curve ( $e$ ); it is omitted to avoid congestion. All the curves were

pendular ring saturation zero†.

computed from the pore size distribution given in Table 3. The marked effect of the entry-exit arrangements is clearly displayed. A wide range of composite curves can be generated by selecting one sequence up to the common point, and another sequence for the remainder of the curve.

**Comparison with experiment.** All curves have a common point at pore rank 6 (saturation,  $S = 37.5$ ), force rank 6 (scaled pressure,  $P_s = 0.41$ ); this provides a point for purposes of comparison between calculated and experimental data. As a consequence of working with scaled values, the saturation axis remains unchanged. To express the scaled pressure in terms of the dimensionless group  $PR/\gamma$ , substitute  $V_s = cV/R^3$  into equation (4) whence:

$$\frac{P_t R}{\gamma} = 13.75 \left[ \frac{c}{V_s} \right]^{0.775}$$

but  $V_s \propto 1/P_s$ , hence:

$$\frac{P_t R}{\gamma} = 13.75 [c_m P_s]^{0.775}$$

where  $c_m$  is a modified scale factor.  $PR/\gamma$  for  $c_m = 1$  is plotted with  $P_s$  on the left-hand axis of Fig. 1 for comparison purposes. Three sets of data for glass spheres<sup>9-11</sup> are also plotted with their appropriate  $PR/\gamma$  scale;  $c_m$  was chosen for coincidence at the common point. The close correspondence between the experimental curves incidentally supports a correlation based on the ratio of pressure deficiency at any saturation, to the pressure deficiency at some fixed saturation<sup>11,12</sup>. It is seen that the experimental section below the common point crosses the theoretical curves\*, and entraps less fluid than the torus arrangement. By inspection, sequence (f) was inferred, which corresponds closely to the experimental points except near the entry pressure (where the experimental values are themselves different), and at the point  $P_s \sim 0.5$ . The details of possible interaction between pore size distribution and entry-exit configuration are clearly in need of elucidation.

**Imbibition.** On relaxing the suction the wetting phase imbibes in the reverse sequence to desaturation, though not at the same pressure deficiencies. Thus, no displacing phase entrapment occurs. For any two cells  $A$  and  $B$  ( $A > B$ ) the condition given by the inequality:

$$AP_b < BP_b < AP_t < BP_t$$

leads to a simple hysteresis loop; likewise the present model exhibits a desaturation-saturation cycle. Having traced a desaturation curve, the pressure deficiency axis for the imbibition curve may be calculated from equation (5). The ratios of pressure deficiency for imbibition to that for desaturation,  $P_b/P_t$ , associated with  $P_t R/\gamma$  values, are respectively: 0.61, 4; 0.55, 5; 0.51, 6; 0.48, 7; 0.45, 8; 0.43, 9. Experiment indicates this ratio to be roughly 0.5, so the theoretical values are of the correct order.

\* The situation may be better than indicated here. As will be seen next, with the present model no displacing phase entrapment occurs on imbibition. The curves are thus analogous to the secondary desaturation and the pendular imbibition curves<sup>12</sup>. The former are similar in appearance to the torus configuration curve (d) at pressure deficiencies below the common point.

The model requires refinement to represent scanning curves<sup>13,14</sup> (secondary desaturation and imbibition); a two-cell configuration (parallel arrangement) exhibiting an elementary scanning curve occurs when:

$$AP_b < BP_b < BP_t < AP_t$$

**Further investigations.** The square was used in a manner designed to simulate a drainage column. A suction gradient equivalent to a gravitational field increasing by one rank per row up the square was inherent in this model, and it was imagined that the wetting phase exited at the bottom edge of the square while the displacing phase entered at the top edge (one example of arrangement (a)). The gradient was balanced by a positive pressure which was relaxed one rank at a time allowing the column to drain. Eventually, a pressure deficiency was applied to complete the emptying sequence. Further work is required to elucidate the details; however, the results did not correspond to arrangement (a). Instead, they appeared to be more akin to arrangement (b) at the entry pressure, then somewhat between (d) and (f) up to pressure rank 6, and finally, at higher pressures were similar to arrangement (c).

Two refinements which could improve all network models concern the processes preceding the sudden emptying and filling of pores: (1) as the suction builds up to  $P_t$  the meniscus curvature increases and consequently a small quantity of liquid is withdrawn from the cell; when cumulated this leads to the steep slope extending from complete saturation to the entry suction, and would also help smooth the step nature inherent in the present models where relatively few pores are used; (2) as the suction is relaxed to  $P_s$  a quantity of liquid enters the cell; this could be as high as half the cell volume.

This investigation is being extended to a  $20 \times 20$  matrix; first results are generally similar to those from the  $10 \times 10$  matrix, with some local deviations of between 1/4 and 2 pores.

A three-dimensional model would provide a more appropriate representation of a packing. Arranging the rows or columns of a Latin square in cyclic order will lead to squares which can be assembled, layer by layer, into a simple model.

## PACKING ARRANGEMENT OF TROPICOLLAGEN MOLECULES

By DR. JAMES W. SMITH

Department of Anatomy, St. Salvator's College, St. Andrews

THE work of Highberger *et al.*<sup>1</sup>, Gross *et al.*<sup>2</sup>, Schmitt *et al.*<sup>3</sup> and Hodge and Schmitt<sup>4</sup> has led in the past decade to the theory that native collagen fibres are aggregates of tropocollagen molecules, each of which is about 2600 Å long and 15 Å in diameter. The molecules are similarly orientated and arranged so that each is staggered by a quarter of its length in relation to those molecules which abut immediately against it. This theory has been

supported by the demonstration of tropocollagen molecules of the forecast dimensions<sup>5,6</sup>, by the discovery that sonic irradiation disrupts such molecules into halves and quarters<sup>7</sup> and by the photographic synthesis of native collagen periodicity from the segment long spacing pattern<sup>8</sup>.

Recently, however, the complete validity of the theory has been questioned by some authors<sup>9,10</sup>. The theory is

usually illustrated in a two-dimensional sense by a diagram such as that in Fig. 1*a* showing all adjacent molecules quarter-overlapped in relation to immediately adjacent molecules. But consideration of the problem in three dimensions shows immediately that the simple arrangement visualized by the theory is a geometrical impossibility. Thus, if *A*, *B* and *C* in Fig. 1*b* represent three adjacent molecules in the same plane, *A* is in contact with *B* and *B* with *C*, but *C* is not in contact with *A*, and therefore *A* can be quarter-overlapped on *B* and *B* can be quarter-overlapped on *C*. But if the same molecules are packed as in Fig. 1*c*, as they would be in any actual fibre, each molecule is in contact with the other two. If molecule *A* is represented in Fig. 1*d* by *A*, then, allowing for a quarter-overlap, the position of molecule *B* must be that represented by either *B*<sup>1</sup> or *B*<sup>2</sup>. Similarly, if molecule *C* is quarter-overlapped on molecule *B*, its position in Fig. 1*d* must be represented either by *C*<sup>1</sup> or *C*<sup>2</sup> or *C*<sup>3</sup>. But *C*<sup>3</sup> is in register with *A* while *C*<sup>1</sup> and *C*<sup>2</sup> overlap *A* by half their length. It is therefore impossible for all molecular contacts to be quarter-overlap in nature in any three-dimensional packing arrangement.

Fig. 1

For the purpose of estimating the number of quarter-overlaps possible in any particular collagen fibre, the hexagonal packing arrangement in Fig. 2, which accommodates the maximum number of molecules per cross-sectional area, has been used. Its use is, of course, purely a convenience, and does not infer that the collagen molecule is hexagonal in shape. The same packing arrangement could be formed with circles, each circle occupying the interior of a hexagon. In this packing, the molecules are arranged in successive rings around a central molecule and for convenience alternate rings have been stippled in Fig. 2. The first ring consists of six molecules and thereafter the number of molecules in each additional ring increases by 6 (Table 1). As each ring is added to the fibre its molecules can be regarded as forming two groups of contacts. The contacts between the members of the added ring are equal in number to the number of molecules within the ring, while the contacts with the molecules of the immediately deeper ring are equal to the number of all the molecules in the two rings concerned. Thus the third ring has 18 molecules, the second 12 molecules, and therefore the number of molecular

No. of molecular ring	No. of molecules in ring	No. of molecules in fibre	Diameter of fibre (Å)	No. of molecular contacts in fibre	No. of quarter-overlaps	% of quarter-overlaps
1	6	7	45	12	9	75.0
2	12	19	75	42	30	71.4
3	18	37	105	90	63	70.0
4	24	61	135	156	108	69.2
5	30	91	165	240	165	68.7
6	36	127	195	342	234	68.4
7	42	169	225	462	315	68.2
8	48	217	255	600	408	68.0
<i>X</i>	$6X$	$3X^2 + 3X + 1$	$30X + 15$	$9X^2 + 3X$	$6X^2 + 3X$	$\frac{100(2X+1)}{3X+1}$
13	78	547	405	1,560	1,053	67.5

contacts established, as the third ring is added, is  $18 + 18 + 12 = 48$ .

It has been found by trial and error that the arrangement of molecules in a longitudinal direction which gives the greatest number of quarter-overlapped contacts between adjacent molecules is that in which each molecule of a ring is quarter-overlapped on the adjacent molecules of the same ring. In these circumstances, of the contacts which the molecules of one ring form with those of the immediately deeper ring, half are quarter-overlapped while the other half are not so related. This arrangement is illustrated in Fig. 2 in which all the quarter-overlapped contacts are indicated by two short cross-lines.

Various features of fibres with this type of molecular packing are tabulated in Table 1. It will be noted that the figures in most of the columns form various types of arithmetical progressions, and as a result the features of a fibre with '*X*' molecular rings can be calculated: these are shown in the penultimate line. Finally, from these expressions, if the diameter of a collagen fibre is known, say, 405 Å, the other features of its molecular arrangement can be readily calculated as shown in the final line.

It is evident from the final column in Table 1 that in a fibre with only one ring of molecules and a diameter of

Fig. 2

Fig. 3

45 Å, 75 per cent of the molecular contacts are quarter-overlapped. As more molecular rings are added this figure falls, making an asymptotic approach to a limiting value of 66.6 per cent (Fig. 3).

These observations do not affect the general concept that the 640 Å periodicity of native collagen is a result of quarter-overlapping among the constituent tropo-collagen molecules. But it does seem of some importance that it should be recognized that in a fibre of average size only 67–68 per cent of the molecular contacts can be of this nature. Moreover, it seems probable that the problem discussed here is closely associated with that of the minimum size of collagen fibre in which cross-striations are evident. Ross and Benditt<sup>8</sup> have calculated that with this type of molecular arrangement cross-striations

would be evident in fibres of 100 Å diameter, whereas if all molecular contacts were quarter-overlapped, striations would be evident in fibres of 70 Å diameter. In practice the minimum fibre diameter exhibiting cross-striations is about 100 Å.

## NEW PHASES IN THE SYSTEM $\text{Al}_2\text{O}_3\text{--SO}_3\text{--H}_2\text{O}$ AT TEMPERATURES ABOVE 100° C

By N. F. DYSON and T. R. SCOTT

C.S.I.R.O. Division of Mineral Chemistry, Melbourne

**S**OLUTIONS of aluminium sulphate (especially 'basic' solutions, in which the molar ratio  $\text{SO}_3 : \text{Al}_2\text{O}_3$  is less than 3) hydrolyse readily at elevated temperatures<sup>1</sup> to produce in most instances the compound  $3\text{Al}_2\text{O}_3 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$  (phase *B*, Table 1). A further survey of the ternary system has now been made over the temperature-range 100°–290° C, at dilutions ranging from 0.1 to 1.0 molar (with respect to  $\text{Al}_2\text{O}_3$ ) and with compositions ranging from normal salt (molar ratio  $\text{SO}_3 : \text{Al}_2\text{O}_3 = 3$ ) to highly basic mixtures or solutions (ratios as low as 0.7). This work has demonstrated the existence above 100° C of at least five compounds, of which two are new (phases *A* and *D*) and another (phase *E*) has not previously been reported from sulphate solutions. The compounds are listed in Table 1 in order of increasing basicity.

Table 1. COMPOUNDS IN THE SYSTEM  $\text{Al}_2\text{O}_3\text{--SO}_3\text{--H}_2\text{O}$  AT ELEVATED TEMPERATURES

Phase	Oxide formula	Structural formula	Name
<i>A</i>	$\text{Al}_2\text{O}_3 \cdot 2\text{SO}_3 \cdot \text{H}_2\text{O}$	$\text{Al}(\text{SO}_4)(\text{OH})$	—
<i>B</i>	$3\text{Al}_2\text{O}_3 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$	$(\text{H}_2\text{O})_2\text{Al}_2(\text{SO}_4)_2(\text{OH})_{12}$	Hydronium alunite
<i>C</i>	$3\text{Al}_2\text{O}_3 \cdot 3\text{SO}_3 \cdot 10\text{H}_2\text{O}$	$(\text{H}_2\text{O})_2\text{Al}_2(\text{SO}_4)_2(\text{OH})_{12}$	—
<i>D</i>	$3\text{Al}_2\text{O}_3 \cdot 2\text{SO}_3 \cdot 11\text{H}_2\text{O}^*$	$(\text{H}_2\text{O})_2\text{Al}_2(\text{SO}_4)_2(\text{OH})_{12}$	Glassy phase
<i>E</i>	$\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$	$\text{Al}(\text{OH})_3$	Boehmite

\* As prepared over the temperature-range 130°–150° C.

It is interesting to note that a general formula,  $(\text{H}_2\text{O})_x \text{Al}_2(\text{SO}_4)_y(\text{OH})_{18+x-2y}$ , includes all phases (except *E*) in Table 1. As yet, however, we have no direct evidence of hydronium ions in phases *C* and *D* and we do not claim that the general formula necessarily indicates a series of closely related crystallographic structures.

A brief account of the conditions under which each compound forms is given here.

$\text{Al}_2\text{O}_3 \cdot 2\text{SO}_3 \cdot \text{H}_2\text{O}$  (*A*) is prepared by heating molar solutions of aluminium sulphate (ratio 2.9) at 290° C for 16 h. It does not appear at much lower temperatures (for example, 250° C) or from more dilute or highly basic solutions. It dissolves very slowly in boiling 5 N hydrochloric acid and loses 'hydroxyl' water only on heating above 550° C.

$3\text{Al}_2\text{O}_3 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$  (*B*) is the compound most commonly encountered over a very wide range of compositions and temperatures (170°–290° C). Although previously called 'hydrogen' alunite by Davey and Scott<sup>2</sup>, it is better described<sup>3</sup> as 'hydronium' alunite, with  $\text{H}_3\text{O}^+$  substituting for  $\text{K}^+$  in the alunite lattice. In the range 100°–170° C a very similar compound containing an extra 2–4 per cent water is encountered, which is probably  $3\text{Al}_2\text{O}_3 \cdot 4\text{SO}_3 \cdot 10\text{--}15\text{H}_2\text{O}$ , as described by Okabe<sup>4</sup>.

$3\text{Al}_2\text{O}_3 \cdot 3\text{SO}_3 \cdot 10\text{H}_2\text{O}$  (*C*) is formed in preference to phase *B* in more basic solutions and has been encountered at all temperatures in the range 100°–180° C. At the higher temperatures phase *C* is metastable with respect to *B* and is gradually converted to the latter over a period of several hours. Phase *C* gives a characteristic X-ray diffraction pattern which is related to that for the compound  $\text{Al}_2\text{O}_3 \cdot \text{SO}_3 \cdot 4\text{H}_2\text{O}$  described by Bassett and Goodwin<sup>5</sup>. The difference in water content may be ascribed to the fact that the latter compound was analysed in the air-dried state.

$3\text{Al}_2\text{O}_3 \cdot 2\text{SO}_3 \cdot 11\text{H}_2\text{O}$  (*D*) is an unusual material with a somewhat variable composition. The empirical formula given in Table 1 is averaged from preparations made by heating very basic solutions in the temperature range 130°–150° C. Below this temperature the water content shows a marked increase, but the  $\text{SO}_3 : \text{Al}_2\text{O}_3$  ratio does not change significantly. Phase *D* is usually found in preparations heated at temperature for a relatively short period, since it is nearly always metastable with respect either to phase *C* or to that form of phase *B* with the higher water content. It is optically isotropic and structurally amorphous in X-ray diffraction tests. We therefore describe it as 'the glassy phase' and it is undoubtedly related to a similar material obtained by Bassett and Goodwin<sup>5</sup> from their 'two-liquid system 1' at temperatures below 100° C.

$\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$  (*E*) has only been identified at temperatures above 190° C as a product of dilute and highly basic solutions. So far, it has always been obtained in admixture with phase *B*, from which it can largely be separated by selective solution of the latter with boiling 5 N hydrochloric acid. Phase *E*, though relatively resistant to solution in acids, is poorly crystallized but can be readily identified as boehmite by X-ray powder diffraction techniques. It is worthy of note in this connexion that well-crystallized boehmite with a very sharp XRD pattern has been prepared by us at temperatures below 190° C from basic solutions of either aluminium chloride or aluminium nitrate.

In the related system  $\text{Fe}_2\text{O}_3\text{--SO}_3\text{--H}_2\text{O}$ , phases analogous to our phases *A*, *B* and *E* have been described by Posjank and Merwin<sup>6</sup>. The respective iron compounds, however, start to form at much lower temperatures than their aluminium analogues. We have prepared the iron compounds  $\text{Fe}_2\text{O}_3 \cdot 2\text{SO}_3 \cdot \text{H}_2\text{O}$ ,  $3\text{Fe}_2\text{O}_3 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$ , and  $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$  by heating the appropriate ferric sulphate solutions and have shown them to be isomorphous with the corresponding aluminium compounds.

We thank Dr. W. G. Mumme for assistance with the X-ray diffraction work.

## BLOOD : BONE EQUILIBRIUM IN CALCIUM HOMOEOSTASIS

By DR. JAMES MACGREGOR\* and DR. WALTER E. BROWN†

Bio-Engineering Unit, University of Strathclyde, Glasgow, and the National Bureau of Standards, Washington, D.C.

THE nature of the dynamic equilibrium between the mineral component of human bone and its ion in solution in tissue fluid is unknown. A few years ago the theory advanced by MacLean and Urist<sup>1</sup> was generally accepted, and experimental investigations of the mode of action of parathyroid hormone<sup>2,3</sup> were designed in terms of it. Their hypothesis held that normal tissue fluids were 'supersaturated' with respect to whole bone; that the bone mineral maintained only 'hypoparathyroid-levels' of calcium and phosphorus by physical processes and that a parathyroid-controlled 'vital activity' caused destruction of whole bone, release of mineral and increase in the concentration of calcium in the tissue fluids. Maintenance of a calcium concentration gradient therefore not only required continual secretion of parathormone but also continual osteoclastic resorption of whole bone.

In 1957, Nordin<sup>4</sup> suggested that the situation be re-examined in terms of solubility theory and showed that calf bone powder would maintain reproducible levels of calcium and phosphorus *in vitro*. Later, MacGregor and Nordin extended the work and showed that, in both trihydroxymethylaminomethane : hydrochloric acid<sup>5</sup> and carbonic acid : potassium bicarbonate buffer systems<sup>6</sup> at ion strengths of 0.15 and at 20° C, human dead bone powder would maintain the levels of calcium and phosphorus found in normal tissue fluids if the pH at the solid/solution interface was about 7.0-7.1 (ref. 6). This pH is intermediate between the intracellular pH of 6.8 and the extracellular pH of 7.4, and the concept of a pH gradient across the blood : bone barrier is not unattractive.

The equilibration investigations showed that the ion-concentration product,  $[Ca^{++}]^3[PO_4^{--}]^2$ , expressed as a negative logarithm ( $pK$ ) was relatively constant over the pH range 6.4-7.6 and ranged from 26.0 to 26.8 and was not related to pH. On the other hand, the ion-concentration product,  $[Ca^{++}][HPO_4^-]$ , correlated highly with pH (ref. 5). On this evidence, MacGregor and Nordin postulated that, on purely empirical grounds, the cubed-squared product best represented the physico-chemical relation between normal human bone and its ions in 'equilibrium' with it. It was pointed out that no theoretical significance could be attached to the tricalcium phosphate product on this basis and that the authors did not necessarily consider that this salt was the relevant solid phase of 'the exchangeable calcium pool'.

The chemical nature of the micro-crystals in bone and the physical properties of its surfaces have been the subject of discussion for many years. The conventional view<sup>7</sup> is that hydroxyapatite (HA) is the relevant compound. The basic model is modified in detail by internal lattice faults with entrapped contaminants, and the free surfaces are believed to have suffered heteroionic exchange with ions such as  $Sr^{++}$ ,  $Mg^{++}$ ,  $Na^+$ ,  $P^-$ ,  $CO_3^{--}$ , and citrate. In consequence, quantitative analysis of whole bone has yielded no definitive data.

In view of the possibility that one or more sparingly soluble calcium phosphates  $\{Ca_5OH(PO_4)_3, Ca_8H_2(PO_4)_6-$

$5H_2O, \beta-Ca_3(PO_4)_2, CaHPO_4, CaHPO_4 \cdot 2H_2O\}$  could be present in bone, assumptions regarding the stoichiometry of the equilibrium between the solid phase and the aqueous solution are undesirable. It is easily shown<sup>8-10</sup> that solubility data can be treated in a way so that such assumptions become unnecessary. The formula for any calcium phosphate may be written in generalized empirical form as  $Ca_xH_y(PO_4)_zH_2O$ , where  $2x+y=3$  and  $y$  may have negative values (for example, for HA,  $x=5/3$ ,  $y=-1/3$  and  $z=1/3$ ). The condition for equilibrium between an aqueous solution and the generalized salt requires that there be no change in free energy for the reaction:

That is, the sum of the chemical potentials of the components given on the left side of the equation is equal to the standard free energy of formation of the salt on the right-hand side.

$$x \mu_{Ca(OH)_2} + \mu_{H_3PO_4} + (z-2x) \mu_{H_2O} = \Delta F_{xx}^0$$

If we then assume that the chemical potential of the water is essentially constant for dilute solutions and that the chemical potentials of  $Ca(OH)_2$  and  $H_3PO_4$  may be expressed as usual in terms of their ionic activities, then:

$$\mu_{Ca(OH)_2} = \mu_{Ca(OH)_2}^0 + RT \ln (Ca^{++})(OH^-)^2$$

$$\mu_{H_3PO_4} = \mu_{H_3PO_4}^0 + RT \ln (H^+)^3(PO_4^{--})$$

and we can derive the result:

$$\log (Ca^{++})(OH^-)^2 = -\frac{1}{x} \log (H^+)^3(PO_4^{--}) + K_{xx}$$

where the parentheses represent ionic activities and  $K_{xx}$  is a constant specific to the applicable salt.

Therefore if negative  $\log (Ca^{++})(OH^-)^2$  is plotted against negative  $\log (H^+)^3(PO_4^{--})$  for a series of solutions in equilibrium with the above salt, the points should fall on a straight

line with a slope of  $-\frac{1}{x}$ , where  $x$  is the Ca/P molar ratio in the salt. In other words, the slope is dictated by the stoichiometry of the reaction. The position of the line is determined by the value of  $K_{xx}$  which cannot be calculated without assumptions concerning the appropriate activity co-efficients. However, in a series of experiments at constant ionic strength it is usually assumed that the activity co-efficients are also constant, and therefore the slope of the line is valid even though its position is made somewhat obscure by the replacement of  $Ca^{++}$  and  $PO_4^{--}$  ion activities by their concentrations.

This method has been applied to the results of MacGregor and Nordin<sup>5</sup> and MacGregor<sup>11</sup>. In the first case negative  $\log (Ca^{++})(OH^-)^2$  was plotted against negative  $\log (H^+)^3(PO_4^{--})$  using the data from experiments in which adult dead bone powder was equilibrated with *tris* and cacodylate buffers. Unitary activity co-efficients were assumed for the calcium and phosphate ions. The graph is shown in Fig. 1. The slope of the line of best fit obtained by linear regression analysis was -0.616 which represents a Ca/P ratio for the solid phase of 9.72/6.

Secondly, the results of experiments with child dead bone powder were treated by this method and the results are shown in Fig. 2. In this case the slope was -0.743 representing a Ca/P ratio of 8.10/6.

Fig. 1. Chemical potential relation in equilibration investigations with powdered adult bone

Fig. 2. Chemical potential relation in equilibration investigations with powdered child bone

It would appear then that in the child the solid phase in equilibrium with body fluids is octocalcium phosphate (OCP),  $\text{Ca}_8\text{H}_2(\text{PO}_4)_6 \cdot 5\text{H}_2\text{O}$ , while in the adult the Ca/P ratio of the equilibrating solid phase is more nearly that of HA. This interpretation is dependent on the degree of confidence we can place in the slopes of the fitted lines.

A correlation analysis yielded regression co-efficients and standard errors for adult and child dead bone listed in Table 1. Given also is the Ca/P ratio (that is, the reciprocal of the regression coefficient) in each instance and the limits in the ratio Ca/P at the 95 per cent confidence-level.

Bone	Regression coefficient	S.E.	Equivalent Ca/P	95% confidence limits of Ca/P
Adult	-0.616	0.018	9.72/6	9.24/6, 10.32/6
Child	-0.743	0.018	8.10/6	7.62/6, 8.52/6

The Ca/P ratio derived from the adult-bone results corresponds quite closely to that of HA, 10/6. The ratio 9/6 is outside the 95 per cent confidence limits, and it is extremely unlikely that the true slope could correspond to 8/6, the ratio for OCP.

The results indicate that the solid phase saturating the solutions in the experiments with child bone is OCP, but they should not be construed to mean that bone salt in children is exclusively OCP. The behaviour is also consistent with the view that the major phase is unreactive or does not have a definite solubility, while OCP—even though a minor phase—governs the apparent solubility. It has been shown in fact that the rates of dissolution and recrystallization of OCP appear to be considerably greater than those of HA<sup>12</sup>.

Other indications support the idea that OCP may be present in bone. The 'platey' habit of crystallites in bone has been interpreted as indicating that OCP participated in their formation<sup>12</sup>. Evidence has been presented recently to support the view that growth of HA crystals depends on a mechanism in which OCP is

the initial precipitate<sup>13,14</sup>. The incorporation of phosphate into the apatite lattice has been shown by Dallemagne *et al.* to involve initially an acidic phosphate which we believe is OCP<sup>15</sup>. On the other hand, the adult bone results indicate that HA probably dominates the equilibration in aged formed bone.

Thus, the burden of evidence now available supports our considered view that bone mineral is first formed as OCP and that there are spontaneous ageing changes (hydrolysis) which convert OCP into HA. In the child, where bone growth is maximal, there tends to be more OCP in the microcrystals than in the older subject where the reorganization of the OCP to HA overtakes the precipitation process.

Since the new feature of our theory concerns the presence of OCP in 'young' bone, we have applied the calculation to the results of Nordin<sup>4</sup>, who examined the equilibration of powdered calf bone with 0.15 M *tris* and cacodylate buffers at 37° C (Fig. 3). His results yielded a regression coefficient of -0.738 with a standard error of 0.026 and 95 per cent confidence limits of 7.56/6 and 8.82/6. This regression coefficient represents a Ca/P ratio of 8.13 : 6. It is highly improbable that this observed ratio could have arisen by chance if the true Ca/P ratio was 7/6 or 9/6. This confirms the dominance of the OCP stoichiometry in equilibrations with 'young' bone.

Fig. 3. Chemical potential relation in equilibration investigations with powdered calf bone

Since there appears to be a difference in the physico-chemical behaviour of young and adult bone, it may be possible to explain the raised serum inorganic phosphate concentrations in children by the greater solubility of OCP as compared to that of HA. MacGregor and Nordin were aware that their 'ion product' theory of blood : bone exchange and the role of the parathyroid glands in maintaining the level of the equilibrium<sup>16</sup> might not explain adequately the situation in child plasma. Possible explanations advanced by MacGregor<sup>17</sup> included the suggestions that child plasma might contain a larger proportion of calcium and phosphorus binding substances, that the metabolic pH gradient between the bone mineral tissue fluid interface and the circulating body fluids might be steeper due to increased metabolic activity in the young, or thirdly, that there might be a qualitative difference in child bone. The last-mentioned now appears more plausible, and explains the observed differences, at least in part.

Our present ability to re-interpret the results for child bone, which to some extent conflicted with the 'solubility' hypothesis of parathyroid function, now yields substantial support to that thesis, since it allows rational explanation of the fact that plasma inorganic phosphates in young mammals are higher than in adults, whereas the plasma calcium concentration is usually fairly constant at about 2.5 mM. In point of fact it is the calcium homeostasis which is the specific necessity for optimal cellular function.

The biological significance of these findings remains to be examined in detail. They suggest that OCP is present in greatest amounts in newly formed bone, whether child or adult, and that the chemical properties and interactions of two crystalline species must be taken into account for a full understanding of bone growth and remodelling, bone healing, and various pathological conditions.

In a sense this article can only be a preliminary communication on the basis of retrospective analysis of equilibration data. It is now necessary to re-examine this line of enquiry. In particular, the pure salts should be subjected to the same chemical treatment as the bone powder to verify the position of the fitted lines as well as their slopes. Regardless of the uncertainty suggested by this point, the present evidence for the presence of OCP *in vivo* is substantial and it introduces a new factor of considerable physiological potential. Far from detracting from the concept of a metabolic process modulating a physico-chemical exchange mechanism, these data may now help to explain many of the inconsistencies previously observed with the *in-vitro* models of skeletal behaviour.

We thank Mr. J. W. McInnes, statistics officer to the U.K. Western Regional Hospital Board, for advice on the statistical treatment of these results.

## RELATIVE BIOLOGICAL EFFECTIVENESS OF 592-MeV PROTONS ON MICE

By DR. J. BAARLI

CERN (European Organization for Nuclear Research), Geneva

AND

DR. P. BONÉT-MAURY

Institut du Radium, Paris

THE relative biological effectiveness (RBE) of high-energy protons has been investigated by exposing mice in the external proton beam of the CERN 600-MeV synchro-cyclotron. The proton beam followed the normal beam path in air, as is shown in the beam layout diagram (Fig. 1). The protons, after leaving the cyclotron, were focused by a pair of quadrupole lenses and deflected through 25° into the beam channel of the main machine shielding. Outside this shielding, the protons passed through another bending magnet which deflected the protons 27° in the opposite direction to remove unwanted radiation and to select the protons of a defined energy of 592 MeV. Another quadrupole lens was placed in front of this magnet to de-focus the beam in order to maximize the radiation field size at the place of irradiation. For the same reason, the irradiation site was chosen as far as possible away from the beam focus (18 m), immediately in front of a 10-m deep beam catcher.

The beam intensity was monitored with a secondary emission ionization chamber calibrated to measure total beam intensity<sup>2</sup>. The intensity distribution in the beam at the site of irradiation was determined using a 0.6-cm<sup>3</sup> air-filled ionization chamber (Ionex Baldwin Industrial Control, Dartford, Kent), mounted on a *x-y* scanning frame. This chamber had previously been calibrated with 600-MeV protons by comparison with a tissue-equivalent ionization chamber of the Rossi type<sup>3</sup>.

A rotatable disk 1 m in diameter, made of 0.3-cm 'Lucite', placed perpendicular to the beam direction was centred in the beam. Small perforated 'Lucite' mouse cages were attached to the disk with their axes parallel to the beam direction. Dose-rates were selected by fixing the mouse cages at various radii on the disk.

The dose-rate measurements were made by the ferrous-ferri dosimeter<sup>4</sup>. Small thin-walled sealed-off glass

tubes, 5 cm long and 1.2 cm in diameter, half-filled with the ferrous solution, were placed in the mouse cages. A 0.6-cm<sup>3</sup> ionization chamber was attached to the rotation disk at the same radius as the mouse cages. A second 0.6-cm<sup>3</sup> chamber was placed at the side of the beam to control any directional displacement of the beam during irradiation. The secondary emission chamber was used as the reference monitor.

Dose-rate measurements were first made at different radii with the disk rotating at a speed of 3 r.p.m. These measurements were used to centre the wheel in the beam. The relative dose-rate at various distances from the centre of the rotating wheel is shown in Fig. 2. By exposing the ferrous-ferri system and the Ionex ionization chamber simultaneously in the 600-MeV proton beam at the same radii, an agreement within 5 per cent of the measured dose was observed with these two instruments. A factor of 0.93 was used to convert the ferrous-ferri system readings to rad.

Male mice, 57 days old, of pure strain (C57B66), weighing on the average  $22.4 \pm 0.5$  g, were exposed. They were placed in the 'Lucite' tubes described here. The tubes were perforated to assure sufficient air circulation to the animals during exposure. The mouse cages were attached at 6 cm from the centre of the rotating disk and the animals irradiated along their antero-posterior axes with a dose-rate of 361 rads/min.

Six mice were exposed to each of the following doses: 600, 700, 800, 900 and 1,000 rads. For the 600-, 800- and 1,000-rad exposures, a ferrous sulphate dosimeter, used by the Institut du Radium and consisting of glass tubes of mouse-like dimensions filled with a solution of ferrous sulphate<sup>4</sup>, was irradiated simultaneously with the mice at the same radius on the disk. The difference between the chemical dosimetry made at CERN and the ferrous

Fig. 1. Beam layout for the 600-MeV extracted proton beam of the CERN Synchro-cyclotron used for animal experiment

sulphate dosimetry of the Institut du Radium was less than 5 per cent ( $G = 15.6$ ).

After irradiation, the irradiated and control mice were kept under the same conditions and the following parameters recorded: (1) mortality statistics ( $LD_{50}$  and median survival time); (2) weight of the animals; (3) weight of organs sensitive to radiation: spleen, thymus, testicles; (4) haematological tests; white and red cell counts and differential white cell counts.

Mice of the same stock were also irradiated with X-rays, 250 keV (filtration: 2 mm aluminium + 0.3 mm copper), and at a dose-rate of 80 rads/min and tested in the same way for comparison.

The mice irradiated with 592-MeV protons showed the same symptoms as those irradiated with X-rays, that is, loss of weight, alteration of the fur, diarrhoea, blood in faeces, slowing-down of activity for the mice which eventually died, and an increase in weight and resumption of

activity for the survivors. The haematological changes (leucopenia, erythropenia, change of the differential white cell count) were found to be the same for both kinds of radiation, and no anomalous changes were observed in the data relating to 592-MeV protons.

In the dose-range of 600–1,000 rads, 5 of the 9 biological parameters investigated<sup>5</sup> did not show sufficient correlation with the dose to enable numerical values suitable for assessing the RBE to be determined. These were the loss of weight by the animals, the decrease in weight of the spleen on the day of death or on the 30th day, the cell counts and differential white cell counts. The biological variations in the control mice were, however, remarkably small, both with respect to the various weights and to the haematological data recorded.

Blood samples were taken by cutting the end of the tail, each sample being about 8 mg of blood. Such a sample is less than 1 per cent of the total blood volume of the animal but, if samples are taken too frequently (every day during the first 3 days of test, then every 8 days, that is 7 samples in 30 days), this leads to temporary anaemia which is noticeable in the blood counts of the control animals, both in the case of white cells and in the case of red cells (Figs. 3 and 4).

To eliminate as much as possible this additional cause of variation, all the counts made on irradiated animals were expressed as a percentage of those made on the control animals the same day.

For the reference X-rays, it was noted that the development of leucopenia remained approximately the same in the dose-range considered and did not show a significant correlation with the radiation dose. The same applied to erythropenia. Because of leucopenia, differential white cell counts are scarcely possible from the 3rd to the 20th day; inversion occurs on the first day, but the speed or magnitude of this inversion is not clearly correlated to the dose.

Cell counts made on mice irradiated with protons showed the same lack of correlation with dose, so none of the blood tests scheduled gave usable results under the conditions of our experiments; it is likely that this correlation

Fig. 2. Relative dose-rate variation with distance from centre of the rotating wheel exposed to the 600-MeV extracted proton beam

Fig. 3. Variation of erythropenia of mice irradiated with 600 rads, 600-MeV protons. O, Controls; Δ, 600 rads

Fig. 4. Variation of leucopenia for mice irradiated with 600-MeV protons. Δ, 600 rads; ●, 700 rads; ○, 800 rads; +, 900 rads. Top curve controls

would be better for smaller radiation doses using a larger number of animals.

On the other hand, the correlation was satisfactory for the other 4 tests, that is,  $LD_{50}/30$  days, median survival time, testicular atrophy and thymus atrophy on the 30th day.

(1) The  $LD_{50}$  was determined from daily mortality statistics by the probit method<sup>6</sup> and for various periods of observation from the 3rd day, when death began to occur, to the 30th day. An  $LD_{50}$  versus period of observation curve was constructed from these data and the  $LD_{50}/30$  days was determined. With this method, better use can be made of the mortality statistics for high doses, which, in the first days of observation, give mortality rates below 100 per cent (Fig. 5).

For 592 MeV protons, a value of 580 rads for the  $LD_{50}/30$  days was found, whereas the value for the animals exposed to X-rays was found to be 570 rads. In other

Fig. 5.  $LD_{50}$  for mice exposed to 600-MeV protons

words, the  $RBE\ X/P = 570/580 = 0.98$ . The errors of this measurement are estimated to be less than  $\pm 10$  per cent.

(2) The median survival time was calculated from individual survival times observed up to the 30th day, and the dose corresponding to a median survival time of 10 days was determined. This dose was 595 rads for X-rays and 560 rads for protons. The corresponding RBE from this test is  $X/P = 1.06 \pm 0.1$ .

(3) Testicular atrophy in the animals surviving on the 30th day was significant in the range investigated. For mice irradiated with a proton dose of 600 rads, the mean testicular weight was 60.6 mg, whereas it was 193 mg for the control animals; that is, there was a weight loss of nearly 70 per cent. For the X-ray irradiated animals, the corresponding dose was 620 rads. The RBE for these tests was then  $X/P = 620/600 = 1.03 \pm 0.1$ .

(4) For proton irradiated animals given 600 rads, the mean weight of the thymus on the 30th day was 24.4 mg against 53 mg for the control animals, that is, a loss in weight of approximately 52 per cent. The same loss in weight was observed for the X-irradiated mice for a dose of 622 rads. The RBE would therefore be  $X/P = 622/600 = 1.01 \pm 0.1$ .

The agreement between the RBE values from these four tests of different biological significance is rather remarkable, although these experiments are only preliminary and related to a small number of animals. The values of RBE found are a little greater than the value of 0.77 found for mice of different breeds irradiated with 152-MeV protons<sup>7</sup>. However, all the values are near to 1. It should be pointed out that the RBE value may vary with dose-rate<sup>8</sup>.

These experiments confirm that the RBE of near relativistic protons depends mainly on their linear energy transfer (LET) values. When 692-MeV protons enter tissue-like material, the LET is about 250 eV/ $\mu$ , whereas it is 550 eV/ $\mu$  for 152 MeV protons. These LET values are in the LET range of cobalt-60  $\gamma$ -rays and X-radiation<sup>7</sup>.

No peculiar biological effect which might be attributed to 'hot spots', corresponding to nuclear stars, could be detected in our observations. The possibility cannot be excluded, however, that less easily detectable phenomena (such as rare or late occurrence of cancer and genetic anomalies due to these 'hot spots') may later be discovered due to improved methods of investigation, particularly at cellular level.

We thank Mme. Kahn, Dr. Goebel, Mlle. Deysine, Mr. Sullivan, Mme. Cohen-Weill and Mr. Larson for their help, and also the Synchro-cyclotron Division of CERN for running the machine during these tests.

## REDUCTION OF RADIATION DAMAGE TO THE INTESTINAL MUCOUS MEMBRANE BY LOCAL HYPOXIA

DR. B. LARSSON and DR. S. STÉNSEN

Gustaf Werner Institute, University of Uppsala, and Institute of Pathology II, University of Umeå, Sweden

**T**O-DAY the most effective means known for reducing the sensitivity of living tissue to damage caused by ionizing radiation is reduction of the oxygen tension during irradiation. As early as 1909 Schwarz<sup>1</sup> found that ischaemia of the skin may, to some extent, prevent X-ray-induced erythema. Since then many investigators, notably Read and Thoday<sup>2</sup> and Gray *et al.*<sup>3</sup>, have given evidence that the dose-enhancing effect of oxygen, usually referred to as the 'oxygen effect', is an almost invariably present and most significant factor when living materials are being irradiated by ionizing radiation of low linear energy transfer (LET). So far there is no detailed explanation of this effect, but much attention is being paid to the hypothesis of Howard-Flanders<sup>4</sup> that the unpaired electrons of molecular oxygen might combine with the unpaired electrons appearing in the molecules split or ionized by radiation, so as to make radiolesions of the biochemical level irreversible. The possibility of increasing the lethal dose at whole-body irradiation by hypoxia has also been tested experimentally<sup>5,6</sup>. Thus, mice irradiated under nitrogen asphyxia availed themselves of a factor of 2.4 in effective dose reduction.

We have investigated the possibility of reducing acute radiation damage to the rectal mucous membrane by creating a state of local hypoxia in this region during irradiation.

Female albino rats of the Wistar strain weighing 200–250 g were used. Eleven animals were irradiated with a well-collimated 187-MeV proton beam<sup>7</sup> (LET at the rectal level = 0.5 keV/ $\mu$ ) and eight animals with  $\gamma$ -rays (mean LET = 0.2 keV/ $\mu$  from a 50-c. cobalt-60 source<sup>8</sup>). The whole abdominal cavity was irradiated uniformly at a dose rate of 200–300 rads/min. Before irradiation a thin rubber catheter, perforated 1 cm from its closed tip, was introduced about 5 cm into the rectum of the anaesthetized rat via the anus. The catheter was fixed about 0.5 cm from its end through a silk suture carefully applied around the rectum. Another small suture was used to mark the position of the temporary rectal stenosis thus provided. Treatment aiming at the removal of oxygen from the mucous membrane between the anus and the sutures was started 5 min before irradiation by injection of 1 ml. concentrated norepinephrine ('Norexadrin' 1 mg/ml., Astra, Södertälje, Sweden) through the catheter. 1 min later, continuous rectal injection of a reducing solution (0.1 M sodium sulphite in tap water) was started and continued until the end of irradiation. Finally, the stenosing suture and the catheter were removed and the abdominal incision closed.

Two  $\gamma$ -irradiated rats died four days after irradiation with signs of radiation sickness, and they were excluded from the investigation because of post-mortem changes. The other animals were killed 2–5 days after irradiation and specimens for histological examination were taken from the rectal wall in the areas situated 1 cm caudal (specimen *a*), and 1 cm cranial (specimen *b*) to the borderline between the 'deoxygenated' and the 'normally oxygenated' intestinal segments. The following grading

of the radiation-induced damage of the mucous membrane was attempted:

(a) Grade 0: Normal rectal wall (Fig. 1A) the long straight crypts of Lieberkühn of which show narrow lumina with high columnar goblet cells, apparently actively secreting.

Fig. 1. Photomicrographs showing the rectal mucous membrane of a rat, 71 h after irradiation with 2,000 rads of  $\gamma$ -rays (van Gieson stain  $\times 70$ ). A, Grade 0 damage of the 'deoxygenated' part of the rectum; B, grade ++ damage of the 'normally oxygenated' part of the rectum.

Table 1. SEMI-QUANTITATIVE COMPARISON OF CHANGES IN 'DEOXYGENATED' AND 'NORMALLY OXYGENATED' SEGMENTS OF THE RECTUM OF RATS IRRADIATED WITH PROTONS OR  $\gamma$ -RAYS

Experimental group	Dose in rads	Time (h) after irradiation					
		40-60		80-80		80-100	
		a	b	a	b	a	b
Rats irradiated with protons	1,400			+	++		
	2,000			+	++	+	+++
						+	+++
						+	+++
	2,400			+	++		
				+	++		
	2,800			+	++		
				+	++		
Rats irradiated with $\gamma$ -rays	2,000	0	0	0	++	0	+
		0	+	0	++	0	++

a, section from the 'deoxygenated' part of the rectum.

b, section from the 'normally oxygenated' part of the rectum.

0-5+, signify different grades of radiation-induced changes defined in the text.

(b) *Grade 1+*: The lumina of the bottoms of some of the crypts of Lieberkühn are slightly wide, apparently due to shrinkage of some of the epithelial cells.

(c) *Grade 2+*: The atrophy of the columnar goblet cell epithelium in the crypts of Lieberkühn is exaggerated with the formation of slightly cystic lumina (Fig. 1B).

(d) *Grade 3+*: Most of the epithelium in the mucosa is flattened or desquamated, leaving only small cystic remnants of the crypts surrounded by inflammatory cells. The surface epithelium is severely altered, showing polymorphism and hyperchromasia. A moderate oedema is present in the sub-mucous layer.

(e) *Grade 4+*: The mucosa is thin. The surface epithelium is absent or markedly atrophic and only single isolated epithelium-lined crypt-like structures occur. The sub-mucosa is markedly oedematous and invaded by inflammatory cells.

(f) *Grade 5+*: No epithelial structures occur in the atrophic mucosa which is covered by a fibrinous membrane containing granulocytes and cellular debris. Most of the mucosa is converted into a cellular granulation tissue containing small pools of mucin. The inflammatory cells of the markedly oedematous sub-mucous layer encroach on the muscularis propria, giving a phlegmonous inflammation of the rectal wall.

The sections were assessed blind and independently several times by two investigators.

The results are given in Table 1. In 82 per cent of the cases the changes in the 'deoxygenated' intestinal segments were one or two grades less than in those of the

'normally oxygenated' segments. In 18 per cent there was no clear difference between the two segments. In no case were the changes of the 'deoxygenated' segment more marked than in those of the 'normally oxygenated' one.

Fifteen rats were similarly treated with norepinephrine and sodium sulphite for 40 min without irradiation. Microscopic examination of the mucous membrane of those rats killed 3-38 days after treatment revealed no pathological changes.

The ability of norepinephrine and sodium sulphite to deoxygenate the rectal wall was estimated by electro-polarographic measurements<sup>9</sup> of the oxygen tension in the rectal lumen of normal anaesthetized rats. After introduction of the electrode and when constancy of the initial electrode potential, corresponding to about 20 mm mercury, had been established, cotton soaked in norepinephrine was carefully put around the rectum through an abdominal incision. 1 min later, 0.1 M sodium sulphite solution was dropped on the cotton for about 10 min. The oxygen tension was found to decrease during this treatment to less than 1 mm mercury within 7 min after application of the reducing solution to the exterior of the intestine. The experiment was repeated three times with essentially the same result.

From the results of these experiments we assume the protective effect of local application of norepinephrine and sodium sulphite demonstrated in the early interval after irradiation to be due to the hypoxic state of the tissue during irradiation. A practical consequence of this result might be that rectal damage can be reduced in patients irradiated with seemingly carcinocidal doses of high-energy protons<sup>10</sup> or other ionizing radiation of low linear transfer.

## AN IMMEDIATE EFFECT OF X-RADIATION ON THYMUS CELLS

By D. K. MYERS

Biology Branch, Atomic Energy of Canada, Ltd., Chalk River, Ontario

THE lethal effects of X-irradiation on radiosensitive interphase cells have been investigated extensively with mammalian thymocytes, but the initial sequence of events leading to cell death is still uncertain. In 1959, Creasey and Stocken<sup>1</sup> reported that 'oxidative phosphorylation' in isolated thymus nuclei was rapidly abolished by low doses (25-100 rads) of X-irradiation administered either *in vitro* or *in vivo*. However, no evidence could be obtained for a similar effect of X-irradiation on the nuclei of intact thymus cells, and it was suggested, therefore, that the initial demonstration depended on loss of soluble materials from the isolated nuclei into the aqueous suspending medium following irradiation<sup>2</sup>. Further investigations have confirmed the absence of marked changes in intact thymus cells during the first hour after irradiation<sup>3-5</sup>, even though striking alterations are sometimes seen in the nuclei isolated from these cells<sup>7-12</sup>. Unfortunately the latter results are not always reproducible<sup>6</sup>.

In the investigation described here, an immediate effect of X-irradiation on one constituent of the cell nucleus could be demonstrated without any of the manipulations involved in isolation of the nuclei from irradiated cells.

It was noted previously that irradiation of rat thymocytes increased the speed with which the deoxyribonucleoprotein dissolved to form a gel in 2 M sodium chloride<sup>13</sup>. A similar effect can be demonstrated when using dilute (0.3 M) ammonium hydroxide<sup>14</sup> to dissolve the cells, but these gels have less reproducible results. This phenomenon has now been examined in more detail using 2 M sodium chloride at an alkaline pH and with a chelating agent present to increase the speed of gel formation. 2 ml. of cell suspension containing  $2 \times 10^7$ - $3 \times 10^7$  intact rat thymocytes in a standard Krebs-Ringer-phosphate solution<sup>4</sup> at 0° C were mixed rapidly with 3 ml. of a solution containing 3.33 M sodium chloride, 0.67 M *tris*(hydroxymethyl)aminomethane buffer and 0.084 M tetrasodium ethylenediamine tetraacetate (EDTA; versene) at pH 10.8 and room temperature. The mixture was allowed to stand at room temperature for a given period of time without further agitation and its apparent viscosity was then measured in duplicate by the method of Fisher *et al.*<sup>15,16</sup>. Microscopic examination of these mixtures showed that nearly all the cells disappeared within the first 5 min; since the viscosity continued to

increase markedly for many hours (Fig. 1), any differences in the rate of viscosity increase must be ascribed to differences in the rate at which the deoxyribonucleoprotein from the cell nucleus expanded to form a gel<sup>15,16</sup> in the alkaline sodium chloride solution. Cell suspensions were irradiated at 0° C with a 300-kV X-ray machine operated at 1.5 m.amp, the absorbed doses of X-radiation being measured with a ferrous sulphate dosimeter<sup>17</sup>. All doses, up to 1 krad were delivered in 1 min; higher doses were delivered at a rate of 1 krad/min.

Fig. 1. Increase in apparent viscosity of gels formed from rat thymus cells in alkaline saline solution. The relative viscosities of the gels formed from control cell suspensions (○) and from the same cell suspensions after exposure to 1-krad X-radiation (●) were measured at room temperature at various times after mixing with alkaline saline as described in the text.

The relative viscosities of control and X-irradiated cell suspensions at various times after mixing with alkaline sodium chloride solution are shown in Fig. 1. In these experiments, the cell suspension and alkaline sodium chloride were mixed within 0.5 min after completion of a 1 krad X-radiation exposure. An appreciable alteration in viscosity due to irradiation of the intact cells was measured 0.5 min after mixing with alkaline sodium chloride, that is, within 1 min after irradiation. Since the results were essentially similar whether the cell suspensions were held at 0° C either for 0.5 min or for more extended periods of up to 2 h after irradiation before mixing with alkaline sodium chloride, it can be concluded that the viscosity increase represents an immediate effect of X-irradiation.

The rate of gel formation was appreciably affected by doses down to 35 rads of X-irradiation (Fig. 2). The radiation effect reached a maximum in the region of 1–2 krad; higher doses produced a marked decrease in gel viscosity (Fig. 2), presumably due to degradation of the long deoxyribonucleoprotein chains<sup>13,14</sup>.

This effect of X-radiation could also be demonstrated with cell suspensions prepared from the thymus gland of irradiated rats (Table 1). Cell suspensions prepared within 3 min after exposure of the whole animal to 1-krad X-irradiation exhibited the same increase in speed of gel formation as was observed after X-irradiation *in vitro*, again with little effect on the maximum viscosity of the gel after standing for longer periods in alkaline sodium chloride solution. When the irradiated rats were held for 1.5–7 h before preparation of the thymus cell suspensions, increasing degradation of the deoxyribonucleoprotein became evident (Table 1). A similar degeneration occurred when X-irradiated (1 krad) cell suspensions were incubated at 37° C *in vitro* for various periods of time before mixing with the alkaline sodium chloride solution. These *in vitro* experiments showed no measurable decrease in gel formation after 2, 5 or 10 min incubation of the cells at 37° C; the first small but consistent decrease was evident only after 20 min at 37° C. For the rest, the pattern of changes observed after *in-vitro* incubation of irradiated cells at 37° C paralleled closely that observed *in vivo* (Table 1).

The slow degradation of deoxyribonucleoprotein in intact irradiated thymocytes at 37° C is presumably due

Fig. 2. Effect of X-irradiation dose on the speed of gel-formation from rat thymus cells in alkaline saline. Cell suspensions at 0° C were exposed to various doses of X-radiation and then mixed with alkaline saline solution at room temperature as described in the text. The relative viscosities of the deoxyribonucleoprotein gels were measured 5 min after mixing. The horizontal dotted line indicates the viscosity increase of the same cell suspensions before irradiation.

to enzymatic action. A similar degradation has also been demonstrated by other techniques<sup>5,17</sup> and is associated with gross changes in cell metabolism after 1 or more h at 37° C, either *in vitro* or *in vivo*<sup>4,12</sup>. However, an immediate effect of X-irradiation on these cells does not seem to have been demonstrated previously except in the more time-consuming and somewhat ambiguous experiments on isolated cell nuclei<sup>1,7,8,10</sup>. The work recorded here confirms the tentative conclusion that the nuclei of intact thymus cells are altered immediately after low doses of X-radiation.

Similar effects of X-irradiation can be demonstrated with freshly prepared mixtures of control thymus cells in alkaline saline solution. In this case, the *tris* buffer protects the cell residues against any indirect effects of the radiation<sup>16</sup>. When these preparations were exposed to 1-krad X-radiation 1 h after mixing, the apparent viscosity increased rapidly in much the same manner as it did (Fig. 1) after irradiation of intact cells. The dose-effect curve was also virtually identical with that shown in Fig. 2 for irradiation of intact cells, except that the apparent viscosity increased within 5 min to 3 instead of 6 times the corresponding value for non-irradiated preparations. In these experiments, the cells were no longer visible under the microscope, but presumably the islets of deoxyribonucleoprotein were still relatively intact at the time of irradiation.

If the control preparations in alkaline saline solution were allowed to stand for 10–14 days in order to reach maximum viscosities (Fig. 1) and were then irradiated, low doses of radiation had no appreciable effect on the apparent viscosity of the gel. Higher doses produced a decrease in viscosity which was independent of the time after X-irradiation. This decrease, which corresponds to the right-hand side of the dose-effect curve in Fig. 2, amounted to 50 per cent after exposure to 7 krad.

The increase in speed of gel formation after X-irradiation did not seem to be a general property of all cells. Homogenates of spleen, another radiosensitive organ, reacted in much the same manner as described here for thymus preparations. However, we have not as yet been able to demonstrate any striking effect of low radiation doses

Table 1. APPARENT VISCOSITY OF GELS FORMED FROM THYMUS CELLS AFTER X-IRRADIATION *in vivo*

Time after exposure to 1,000 r. (h)	No. of animals	Viscosity increase at various times after mixing with alkaline NaCl (h)		
		0.083	2	24
Control	14	0.9	1.6	8.3
0.05	9	3.9*	7.7*	12.3*
0.5	6	2.8*	5.4*	9.7
1.5	6	1.6*	3.8*	7.0
3.0	6	1.0	2.3	5.4*
5.0	4	0.4*	0.7*	1.6*
7.0	4	0.3*	—	0.8*

\* These values showed a statistically significant difference ( $P < 0.05$ ) from the corresponding control value.

All viscosities were measured with mixtures of 2-ml. cell suspension containing  $10^7$  cells/ml. plus 3 ml. of the NaCl-*tris*-EDTA solution described in the text.

on gel formation with homogenates of radio-resistant cells such as rat liver, rat kidney and chicken erythrocytes. In the case of the latter tissues, the only clear effect of X-radiation was the usual decrease in apparent viscosity after exposure to doses of 5–10 krad. The reason for this difference between the radiosensitive and radio-resistant tissues is still uncertain. Thymus nuclei do contain much more deoxyribonucleate per gram weight than do liver nuclei<sup>14</sup>, which suggests that the deoxyribonucleo-protein of control thymus cells must be more compactly coiled than that of control liver cells. The relative speed of gel formation in alkaline saline solution also tends to be slower with the thymus preparations. Possibly the molecular arrangement of the constituents of the irradiated thymus nuclei resembles more closely that of control liver nuclei. The data on metabolism of isolated nuclei<sup>1</sup> suggest a similar parallel between irradiated thymus and non-irradiated liver nuclei.

## POLYMORPHISMS IN EGG ALBUMEN PROTEIN AND BEHAVIOUR IN THE EIDER DUCK

By DR. HENRY MILNE

Department of Natural History, University of Aberdeen

AND

DR. FORBES W. ROBERTSON

Institute of Animal Genetics, Edinburgh

**B**IOCHEMICAL polymorphism in animal populations presents several aspects. When the polymorphism is balanced we have the well-recognized problem of the role of natural selection, and this requires a search for correlations between gene frequency and differences in habitat, behaviour, susceptibility to disease and exposure, etc. On the other hand, heterogeneity in gene frequency between populations may often afford a useful indication of reproductive isolation, and the greater the number of loci at which such variation occurs the more precise are the tests for restriction of gene flow. This communication deals with a particularly well-marked example of the latter aspect; it is chiefly concerned with genetic polymorphism in egg-white proteins in the eider duck (*Somateria mollissima mollissima* L.).

Using starch-gel electrophoresis<sup>1</sup> and a two-phase buffer system<sup>2</sup>, and staining with amido-black, Robertson (unpublished) has examined several species of birds to see whether the kind of egg-white differences, reported by Lush<sup>3</sup> for the domestic fowl, commonly occur in wild species and, if so, whether this can be turned to advantage to shed light on the population structure of the species concerned. To ensure freshness, eggs were collected early in the laying season or before incubation had started. Generally one egg per clutch was examined after earlier work had shown that intra-clutch variation was unimportant; the phenotype of the albumen is determined by the genotype of the female parent. The species and the number of females scored in this way were as follows: herring gull (*Larus argentatus argentatus*), 196; lesser black-backed gull (*Larus fuscus graellsii*), 100; gannet (*Sula bassana*), 52; starling (*Sturnus vulgaris*), 30; great tit (*Parus major*), 19; and eider duck, 258. For the two gulls and the eider duck the eggs were collected from several widely separated localities. Only the eider showed evidence of egg-white variation. It is, of course, possible that minor differences were overlooked in the other species, since only one system of electrophoresis was used, but the heterogeneity in the eider duck was so well defined that it was the obvious candidate for further study.

This polymorphism presents an apparently simple Mendelian situation of one locus with two common

alleles which control differences in mobility of two protein types, as shown in Fig. 1. The alleles are referred to as *a* and *b* according to whether the protein they determine moves faster or slower. Equal mixture of albumen from the two alternative single-banded, presumably homozygous, types produces two less intensely stained bands which are indistinguishable from the naturally occurring double-banded, presumably heterozygous, types. In all but one of the samples from different localities, the frequencies of the alternative phenotypes conform to the Hardy-Weinberg distribution and this apparent exception is based on only a small sample (11 individuals). In addition to the three types just described, a fourth phenotype occurs very rarely (3 out of a total of 258 clutches scored) with two bands, one in the anterior position corresponding to the *a* band and the other behind the *b* position, as shown in Fig. 1. This slowest-moving band probably represents the effect of a third allele, *c*. So far no individuals have been found which would be identified as *cc* or *bc*.

Gene frequency has been estimated for five different breeding areas, namely Forvie (Aberdeenshire), Tentsmuir (Fife), and sites in Orkney, Iceland and Holland; the distribution of sites is shown in Fig. 2. The number of females scored and gene frequencies are set out in Table 1, which shows considerable variation between European populations. Excluding the Forvie samples, for the reasons described below,  $\chi^2$  for the differences between the other four localities is 20.9 for 3 degrees of freedom,  $P < 0.01$ . Types *ab* and *bb* were grouped in the analysis since the frequency of the *bb* type is very low. From these data, there is no evidence of a latitudinal cline since the gene frequency at the most southerly site in Fife ( $b = 0.09$ ) is very similar to that in the Iceland sample ( $b = 0.10$ ) and both populations conform to the Hardy-Weinberg distribution. We must now consider the situation in the Forvie colony, for which we have more detailed information.

Table 1. GENE FREQUENCY IN EIDER POPULATIONS

Site	N	Frequency of <i>b</i>
Tentsmuir	24	0.10
Orkney	36	0.35
Iceland	50	0.09
Holland	11	0.09*

\* Significant departure from Hardy-Weinberg distribution.

The breeding population of eiders on the Sands of Forvie is one of the largest, if not the largest, mainland colony in Britain. During summer the present population totals more than 3,000 birds, of which an estimated 1,000 pairs breed. About two-thirds of the population is migratory. The migrant birds leave the breeding grounds in July and August to overwinter apparently in the Firth of Tay. By marking individual birds, Milne (unpublished) has shown that the same individuals migrate south each autumn and return to breed the following spring, while the non-migrant birds remain at Forvie throughout the year. These two groups are referred to as 'migrant' and 'sedentary'. Field study of the sedentary flocks in the estuary of the River Ythan during winter showed that pair formation takes place during the period October–March inclusive, and that by April, when the migrants return, most of the sedentary group are already paired. The migrants pair during the period they are away from the breeding grounds. In three successive years they have been recorded arriving back at Forvie within a period of 2–3 days and 95 per cent were already paired. In view of this field evidence of reproductive isolation we decided to estimate the gene frequency in the two groups, and this posed the problem of distinguishing the nests of sedentary and migrant birds.

The Sands of Forvie National Nature Reserve, in which the eiders breed, is a wedge-shaped area of some 1,700 acres, bounded to the south and west by the estuary of the River Ythan and to the east by the North Sea. In winter most of the sedentary birds are to be found in the estuary with a few along the adjacent coast. Field observations suggested a strong tendency for the sedentary birds to nest on the west side of the moor near the estuary, while the migrants nest on the east side, nearer the sea; they overlap in the middle of the moor and records of marked individuals illustrate this difference (Table 2). In the seasons 1962 and 1963 eggs were collected separately from the estuary and the seaward area and the gene frequencies were compared. In 1962 an additional sample was taken from the middle region where overlapping was expected. Dealing first with the gene frequencies in the successive seasons on the west and east sides of the breeding area, we find no statistically significant difference in gene frequency between seasons within breeding areas (Table 3). The values of  $\chi^2$ , with  $ab$  and  $bb$  grouped, are 0.9 and 2.0 for a single degree of freedom in the estuary and seaward areas, respectively, and so the samples have been combined for the seasons to give a total of 51 and 67 clutches for the alternative groups which are believed to comprise almost entirely sedentary and migrant individuals. The gene frequencies are significantly different in the two groups, being respectively 0.14 and 0.27 for the less frequent  $b$  allele. Combining the  $ab$  and  $bb$  types as before,  $\chi^2$  for 1 degree of freedom = 5.7 ( $P < 0.5 > 0.02$ ). In addition, for season 1962, we have a sample of 19 from the middle region where overlap

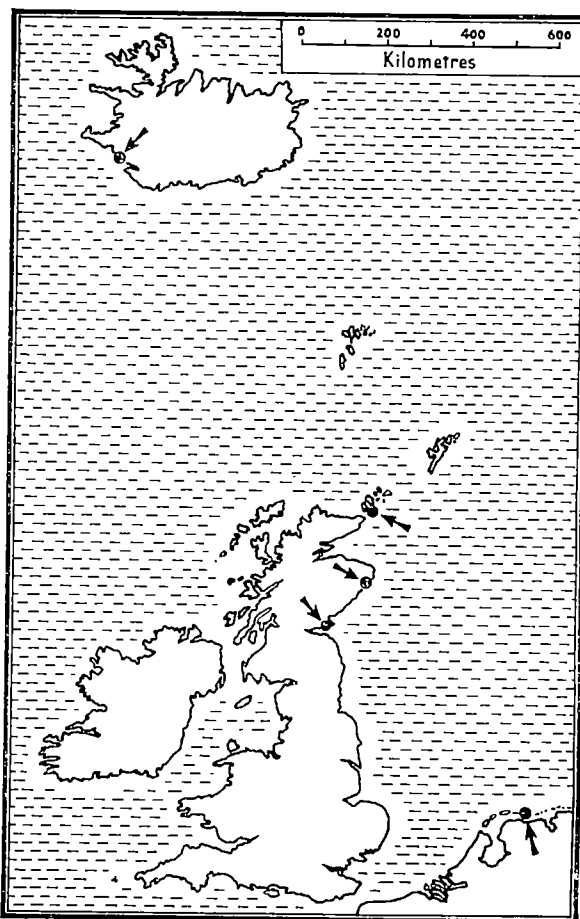

Fig. 2. The distribution of the sites from which eider eggs were collected. The Forvie colony is the more northerly of the two mainland Scottish sites.

occurs, and for this the frequency of  $b$  was estimated as 0.21, an intermediate value which is consistent with the general interpretation. Thus there is excellent evidence of effective reproductive isolation between the two groups of eiders which occupy the Forvie breeding area.

The nature and adaptive significance of this widespread protein polymorphism in the eider are at present unknown, but to clarify the situation the survey is being extended to other populations and geographical races. It would be particularly interesting to know whether there are other races with a high incidence of the  $c$  allele which is so rare in the European populations already sampled. In addition to the protein polymorphism we have also the behavioural polymorphism in the Forvie colony, and it remains to be seen whether this phenomenon also occurs in other colonies. The origin of this behavioural difference, and whether or not it has a genetic basis, is a matter for speculation.

Table 2. NEST SITES OF SEDENTARY AND MIGRANT EIDER DUCK AT FORVIE

	Nesting near estuary	Nesting near sea
Resident on estuary in winter	15	2
Not resident on estuary in winter*	1	14

\* This group refers to marked birds which were never recorded in the estuary during the period November to March inclusive.

Table 3. GENE FREQUENCY IN SEDENTARY AND MIGRANT EIDERS IN THE FORVIE COLONY

Year	Sedentary			N	Frequency of $b$
	$aa$	$ab$	$bb$		
1962	18	3	1	22	0.11
1963	21	7	1	29	0.16
Migrant					
1962	16	12	1	29	0.24
1963	21	12	5	38	0.29
Seasons combined					
Sedentary	39	10	2	51	0.14
Migrant	37	24	6	67	0.27

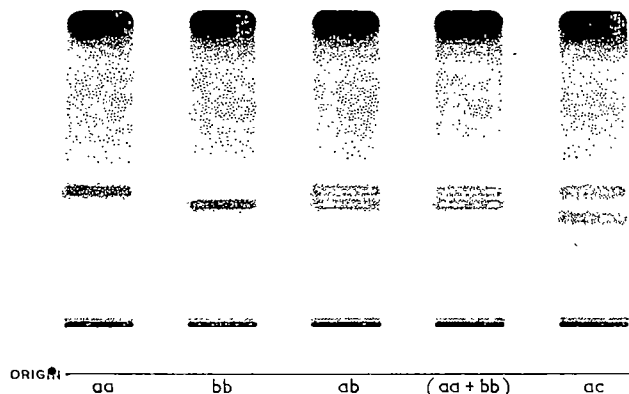

Fig. 1. The appearance presented by the different genotypes in starch-gel section, stained with amido-black. Equal mixture of albumen from the homozygotes is labelled as  $(aa + bb)$ .

Lack<sup>4</sup> has directed attention to the common occurrence of partial migration in various passerine and limicoline species. In the cases considered by Lack, the migrants travel much farther than the migrant eiders, generally to France, Spain and Portugal, while in some species there is a further group which migrates westward to Ireland, that is, the population may be di- or tri-morphic with respect to where the winter is spent. It is not yet known whether heterogeneity in behaviour is a regular feature of eider populations or peculiar to this local population due to particular historical or ecological factors. Conceivably migration might reduce food competition in the more sheltered estuary during winter, so that there could be some advantage to the population as a whole in limiting such (admittedly quite hypothetical) inter-individual competition. In view of their relevance to the stability of population size and density-determining factors, it would be valuable to check the proportions of sedentary and migrant birds in future seasons and record,

at the same time, the frequency of the egg-white alleles in the two groups.

These observations illustrate the advantages of combining ecological and genetic data in the study of animal populations. There is little doubt that the detection of biochemical variation of various kinds will be of great help in the analysis of population structure, not least by providing critical evidence for reproductive isolation in situations where this may be unsuspected or difficult to assess by more usual ecological methods.

We thank the various people who assisted in the collection of eider material or in other ways, especially Drs. H. N. Kluyver and J. Westhoff (Holland), Dr. F. Gudmundsson (Iceland), Mr. E. Balfour (Orkney) and members of the Scottish division of the Nature Conservancy.

## SIMIAN-TYPE BLOOD GROUP FACTORS IN NON-HUMAN PRIMATES

By DR. J. MOOR-JANKOWSKI

Division of Experimental Immunogenetics and Oncology, Yerkes Regional Primate Research Center, Emory University, Atlanta

AND

PROF. ALEXANDER S. WIENER

Office of the Chief Medical Examiner of New York City, Department of Forensic Medicine,  
New York University School of Medicine

IN previous papers<sup>1-3</sup>, observations were described on human-type blood group factors in non-human primates, summarizing the results of two years of investigations of large series of apes and monkeys tested with suitably prepared reagents, originally produced for testing human blood. These tests demonstrated in the red cells and saliva of numerous species of non-human primates the presence of antigens serologically related to or indistinguishable from blood group antigens in man.

At the same time two other parallel investigations have been carried out.

(1) The foregoing procedure of testing of apes and monkeys with human blood grouping antisera has been reversed, that is, iso- and hetero-immune reagents were prepared against red cells of non-human primates<sup>3</sup>, with the view that some might cross-react with human red cells, and, eventually, disclose individual differences in human blood.

The blood factors determined by the reagents so obtained, type specific for the red cells of the homologous simian species, have been designated by us as "simian-type" to distinguish them from human-type blood factors such as A, B, M, N,\* etc., found also in non-human primates<sup>1-3</sup>.

(2) In another series of experiments, various species of primates have been cross-immunized with red cells of one another, in order to produce antisera capable of detecting individual differences in red cells of closely related species of primates including man. Such antisera were expected by us to be type-specific in tests on red cells from species closely related to the homologous red cell donor, while in tests on the homologous donor species, the selective type-specific reaction would tend to be obscured by the stronger, but not type-specific, anti-species reactions.

The type-specific antigen-antibody reactions of such antisera have been designated by us as 'cross-immune' to indicate the special immunological behaviour of reactions

between closely related species, which are different in important respects from other hetero-immune reactions, yet do not fall into the iso-immune category.

The original Rh-factor may be considered the first simian-type blood factor discovered<sup>10</sup>, because the original reagents were prepared by immunization of rabbits and guinea-pigs with rhesus monkey red cells.

More recently, an analogous cross-reacting situation was demonstrated by iso-precipitins produced in baboons, which detected individual differences in sera of man and other primates, while, conversely, human iso-precipitins resulting from blood transfusions detected individual differences in the sera of non-human primates. Moreover, baboons immunized with human sera have produced cross-immune precipitins type specific for sera of man and of other primates<sup>11-13</sup>.

So far observations have been made on simian-type and on cross-immune blood factors in chimpanzees, gibbons and Celebes black apes. The information gained from our previous work on human-type blood groups in these species makes possible a critical comparative evaluation of the newly discovered blood factors.

The purpose of this article is to present a preliminary survey of these most recent findings.

*Chimpanzees.* Individual differences in chimpanzee red cells have been demonstrated with reagents prepared by more than one method.

The first useful reagent proved to be anti-NV lectin from *Vicia graminea* seeds<sup>14</sup>, used in our previous investigations on human-type blood groups in chimpanzees<sup>15</sup>. The so determined human-type blood factor NV plays an important part also in a simian-type blood group system in chimpanzees, as will be shown later.

The second set of reagents was prepared by iso-immunization of chimpanzees. The antisera obtained detected simian-type blood factors designated A<sup>c</sup>, B<sup>c</sup>, C<sup>c</sup> (refs. 16 and 17) and, more recently, E<sup>c</sup> and two antisera temporarily designated as 'John' and 'Bill'. The superscript 'c' indicates the chimpanzee origin of these blood factors, and serves to distinguish them from blood factors of man as well as simian-type blood factors of other primates.

\* To avoid ambiguity, symbols for blood factors and their corresponding antibodies are printed in bold type, symbols for genes and genotypes are printed in italics, and symbols for agglutinogens, phenotypes and blood-group systems are printed in regular type.

Table 1. SIMIAN-TYPE AND CROSS-REACTING PRIMATE BLOOD FACTORS OF NON-HUMAN PRIMATE BLOOD

Species	Source or nature of the reagents	Blood factors found
Chimpanzees <i>Pan satyrus</i>	<i>Vicia graminea</i> seeds and some rabbit hetero-immune anti-human N	N <sup>v</sup> (V)
	Iso-immune chimpanzees	A <sup>c</sup> , B <sup>c</sup> , C <sup>c</sup> , E <sup>c</sup> , John, Bill, Chica
	Cross-immune chimpanzees (immunized with human red cells)	V <sub>1</sub> , Ginga, Mikel
Gibbons <i>Hylobates lar pileatus</i> <i>Hylobates lar lar</i> Celebes black apes <i>Cynopithecus niger</i>	Iso-immune	A <sup>c</sup> B <sup>c</sup>
	Rabbit hetero-immune	A <sup>ba</sup>

Additional type-specific blood factors of chimpanzee red cells have been detected with cross-immune sera from chimpanzees immunized with human red cells. One of these blood factors has proved to be related to the human-type blood factor NV like, in man, blood group A<sub>1</sub> is related to A. Therefore, the factor NV is now called by us v, and the newly discovered simian blood factor is designated as V<sub>1</sub>. The other cross-immune blood factors discovered more recently are temporarily identified by the name of the immune chimpanzees 'Chica', 'Ginga', and 'Mikel' (Table 1).

It is of interest that none of the cross-immune antisera is type-specific for man, but all agglutinate all human red cells tested so far. Perhaps, by selective absorption of the species heteroagglutinins, these antisera can be rendered type-specific for human red cells.

Of the 11 blood factors of chimpanzee red cells shown in Table 1, four are of special interest since they evidently belong to the same blood group system. The four blood factors are V, V<sub>1</sub>, A<sup>c</sup> and B<sup>c</sup>, which determine the system we have designated the V-A-B system of chimpanzees. That the factors V, V<sub>1</sub>, A<sup>c</sup> and B<sup>c</sup> belong to the same blood group system has been established by testing series of chimpanzees and submitting the data to gene frequency analysis<sup>18</sup>. Additional data on which this conclusion is based are shown in Table 2, where the results of tests for blood factor V<sub>1</sub>, A<sup>c</sup> and B<sup>c</sup> on series of 133 chimpanzees are presented. These three factors determine 8 blood types inherited by 6 allelic genes: V<sup>0</sup>, V<sup>A</sup>, V<sup>B</sup>, v<sup>0</sup>, v<sup>A</sup>, and v<sup>B</sup>. Gene frequency analysis shows that the theoretically possible additional allelic genes V<sup>AB</sup> and v<sup>AB</sup> are either non-existent or quite rare. When all four blood factors V, V<sub>1</sub>, A<sup>c</sup> and B<sup>c</sup> are taken into account, then 12 phenotypes can be distinguished, and at least 9 allelic genes v<sup>0</sup>, v<sup>A</sup>, v<sup>B</sup>, V<sup>10</sup>, V<sup>1A</sup>, V<sup>1B</sup>, V<sup>20</sup>, V<sup>2A</sup>, V<sup>2B</sup> may be postulated, determining 45 genotypes.

The serology and genetics of the V-A-B blood group system of chimpanzees are in many ways comparable to that of the Rh-Hr blood types of man. Nevertheless, there appears to be no relationship between the Rh-Hr system in man and the V-A-B system in chimpanzees. Instead, the V-A-B system seems to be the counterpart in chimpanzees of the human M-N-S blood group system. The blood factor V, which holds a key position in the V-A-B system, is detected by anti-NV lectin, which also detects the agglutinin N of the human M-N-S system. Like the tests for human M and N agglutinin, so also the test for V factor of chimpanzee is adversely affected when the red cells are treated with the proteolytic enzyme ficin. Moreover, the serological behaviour of anti-A<sup>c</sup> and anti-B<sup>c</sup> is similar to that of anti-S and anti-s of the human M-N-S system.

It is thus apparent that the V-A-B blood group system of chimpanzees comprises blood factors demonstrable by lectin, by iso-immune sera and by cross-immune sera. This is confirmatory of our hypothesis of the relationship among antigens in closely related species. The next logical step, namely, tests on human red cells with simian antisera, is at present under investigation.

Anti-C<sup>c</sup> serum, in contrast to the antisera of the V-A-B system, reacts well by the ficin technique, and the corresponding blood factor is distributed independently of the V-A-B blood group system. Approximately half the 133 chimpanzees tested so far have the C<sup>c</sup> factor.

Chimpanzees tested for the more recently discovered blood factors E<sup>c</sup>, 'John', 'Bill', 'Ginga', 'Chica' and 'Mikel' shown in Table 2, are still too few in number to allow any definite conclusions as to the relationship of these factors to the V-A-B system, to the C<sup>c</sup> blood factor and to one another. However, it is possible already with the antisera so far developed to distinguish more than 1,000 types of chimpanzee blood.

**Gibbons.** In gibbons (*Hylobates lar lar* and *Hylobates lar pileatus*), antisera of two distinct specificities have been obtained by iso-immunization. The antisera have been designated as anti-A<sup>g</sup> and anti-B<sup>g</sup>, the superscript 'g' representing the gibbon origin of the homologous antigen. So far, only eight gibbons have been available for testing with these reagents, so that no definite conclusions can be drawn as to their relationship.

Among the eight gibbons tested, the simian blood factor of gibbons A<sup>g</sup> is present in seven, and the factor B<sup>g</sup> in three animals.

Tests with anti-A<sup>g</sup> and anti-B<sup>g</sup> on red cells of other primates, including man, have been carried out only to a limited extent and do not permit any valid conclusions.

**Celebes black apes.** Rabbits have been immunized with red cells of Celebes black apes (*Cynopithecus niger*). From one of the rabbit antisera a type-specific reagent has been prepared by selective absorption with red cells of Celebes black apes. The reagent defined individual differences in the red cells of these monkeys and has been designated by us as anti-A<sup>ba</sup>, the superscript 'ba' representing the black ape origin of the homologous antigen. The simian-type blood factor A<sup>ba</sup> has been demonstrated on the red cells of four out of the ten animals tested. Further absorption experiments on other rabbit antisera are being carried out, as well as tests for cross-reacting activity with red cells of other primates.

The results obtained so far on chimpanzees, gibbons and Celebes black apes appear confirmatory of our initial hypothesis. The experiments are being continued.

We thank the following for samples of the animals tested: Dr. Arthur J. Riopelle, Dr. Charles W. Hill and Mr. Frank Shell, of the Delta Regional Primate Research Center of Tulane University, New Orleans, Louisiana; Dr. Clyde H. Kratochvil, Holloman Air Force Base, New Mexico; Dr. Charles W. DeWitt, Department of Surgery, Tulane University, New Orleans, Louisiana; Dr. Maitland Baldwin, National Institute of Neurological Diseases and Blindness, Bethesda, Maryland. Immunization of gibbons was carried out for us at the Delta Regional Primate Research Center.

The work carried out at the Division of Experimental Immunogenetics and Oncology of the Yerkes Regional Primate Research Center, Emory University, Atlanta, Georgia, was assisted by Mr. Charles Guthrie, jun., Mr. Hugh Binley, Mr. Thomas Burke, Mr. Joe Davis and Mr. Barthel Conrath. The work done in the Serological Laboratory of the Office of the Chief Medical Examiner

Table 2. THE V-A-B BLOOD GROUP SYSTEM OF CHIMPANZEES (WIENER THEORY)

Pheno- types*	No. of chim- panzees	Reactions with	Corresponding genotypes
		Anti-V <sub>1</sub> Anti-A <sup>c</sup> Anti-B <sup>c</sup>

## MYCOPLASMA (PLEUROPNEUMONIA-LIKE ORGANISMS) AND BLOOD GROUP I; ASSOCIATIONS WITH NEOPLASTIC DISEASE

By DR. PAUL J. SCHMIDT, DR. MICHAEL F. BARILE and MRS. MARY H. MCGINNIS

Clinical Pathology Department, Clinical Center and Division of Biologics Standards, National Institutes of Health, Bethesda, Maryland

WE have reported that an association exists between the red blood cell group I and neoplastic disease, particularly leukaemia<sup>1</sup>. Whereas normal donors are rarely I negative (< 0.1 per cent), we found 38 of 124 patients with leukaemia to be I negative. Fluctuations in antigen I reactivity during exacerbation and remission in these patients suggested to us that the I antigen was blocked or destroyed during the course of the disease. There is one known relationship between an infectious disease and the I blood group, that is, the cold agglutinins of primary atypical pneumonia often have I specificity<sup>2</sup>. This prompted us to explore the disease relationship we observed in terms of possible association with micro-organisms.

In the work recorded here, 45 microbial agents including mycoplasma (PPLO or pleuropneumonia-like organisms), viruses and bacteria were added *in vitro* to I-positive red blood cells from normal donors to determine whether these agents could alter the I agglutinability of these cells. Eighteen of 25 mycoplasma tested, including three mycoplasma derived from human tumour tissue could block or destroy the I receptors of normal red cells *in vitro* and mimic our findings on patients with leukaemia.

The anti-I reagent was a  $\gamma$ -macroglobulin fraction of an isoimmune serum from an I-negative patient<sup>1</sup>. Parallel control tests were done with a human anti-A<sub>1</sub> (absorbed B) reagent.

The mycoplasma and bacteria were grown in broth medium containing a brain heart infusion base (Baltimore Biologics Laboratory), 15 per cent non-inactivated horse serum and 1 per cent yeast extract, incubated aerobically at 37° C for 3–5 days. The mycoplasma were sedimented by centrifugation at 27,000*g*, re-suspended in physiological saline at a 100-fold concentration and disrupted by freezing and thawing twice before use. The bacteria were sedimented at 8,000*g* and then treated in the same manner. The viral preparations were tissue culture suspensions except for the influenza viruses, which were chick embryo suspensions. They were also exposed to freezing and thawing. These microbial preparations had population titres ranging from 10<sup>7</sup> to 10<sup>9</sup> organisms per ml.

In the test system, one volume of the microbial material was added to an equal volume of a 2 per cent saline suspension of washed day-old I-positive human group A<sub>1</sub> red

cells. The mixture was incubated at 22° C for 30 min and then washed three times in a large quantity of saline and reconstituted to a 2 per cent suspension. One drop of treated cell suspension was mixed with one drop of agglutinating reagent. The tubes were incubated at 22° C for 30 min and centrifuged. Macroscopic agglutination (+++) occurred with saline controls and was used as evidence for no inhibition. Lesser agglutination requiring microscopic examination indicated inhibition and was scored as trace inhibition (++) agglutination) or strong inhibition (+ or negative agglutination). All tests were performed in parallel with cells and reagents from the same lots. Control tests were done using human group AB (non-immune) serum to detect any haemagglutination due to the microbial agents themselves. Broth medium and its yeast component were also tested for activity. After the preliminary experiments, the microbial materials and controls were number-coded before test and duplicate samples were intentionally included.

A total of 45 strains were tested as 58 unknowns for activity in both the I and A blood group systems. These included 25 mycoplasma strains (9 human, 5 murine, 2 avian and 1 each canine, calf and goat, 3 tissue culture and 3 saprophytes), 11 viral agents and 9 bacteria. Seven of the bacteria were non-specifically active, that is, caused pan-agglutination as in the Hubener-Thompson phenomenon<sup>3</sup> when the group AB serum was added. These latter are not listed therefore in Table 1, which shows results of specific activity in the I blood group system of tested material. None of the other agents caused spontaneous haemagglutination with the exception of one influenza strain.

Anti-I agglutination was inhibited by 18 of the 25 mycoplasma strains tested (72 per cent); 7 of the 9 human strains were active (Table 1). One of the 11 viral agents had trace activity. *Streptococcus MG*, an organism used in serological tests for primary atypical pneumonia, was inactive. No inhibition of anti-A<sub>1</sub> was seen. (In other investigations, agglutination by anti-Lewis sera, Le<sup>b</sup> and Le<sup>a</sup>, was not inhibited.)

The I agglutinability of red cells was altered by treatment with mycoplasma material for as little as 30 min. Stronger inhibition resulted when the treated washed cells were held overnight at 5° C. This may explain the vari-

ability of results seen with some of the mycoplasma, especially *M. hominis*, 2, and strain Rab-32.

It was not possible to demonstrate inhibition when mycoplasma were mixed with anti-I before addition of the indicator red cells. This indicates that the effect was not due to serologic cross-reactivity between PPLO and anti-I but was an alteration of the I receptor sites on the red cell.

Cold haemagglutinins are well known in patients with malignant disease of the lympho-reticular system and primary atypical pneumonia. These agglutinins often have anti-I specificity<sup>2</sup>. In primary atypical pneumonia it is presumed that *Mycoplasma pneumoniae*, the causative agent<sup>4</sup>, is responsible for the development of the cold agglutinins. *Mycoplasma pneumoniae* and other PPLO produce haemolysis in culture<sup>5</sup>; others produce haemadsorption<sup>6</sup>.

Mycoplasma have been isolated from human tumour tissue. Horoszewicz recovered mycoplasma strain 880 from the spleen of a patient with chronic lymphocytic leukaemia<sup>7</sup>, and one of us (M. F. B.) isolated mycoplasma strain A63-17 from lung tumour tissue of a patient with Hodgkin's disease and mycoplasma strain RI-12 from tissues of a patient with histiocytoma. These three strains of mycoplasma were among the agents showing the strongest inhibitory activity in the anti-I agglutination system.

Virus-like agents have been demonstrated in cell cultures and virus-like particles seen on electron microscopy of blood and bone marrow from patients with leukaemia<sup>8-12</sup>. Known mycoplasma under electron microscopy using the negative staining technique can appear quite similar to these particles<sup>13</sup>. Dmochowski reports that the blood of leukaemic patients which has virus-like particles also contains mycoplasma<sup>14</sup>. Murphy reported that his agent(s) which produces a fatal leukaemoid disease in mice is either a mycoplasma, an unidentified virus or both<sup>15</sup>.

Our findings suggest that an association may exist between the red cell antigen I, mycoplasma and leukaemia. Of course, it does not follow necessarily that mycoplasma are involved in the pathogenesis of this disease. Mycoplasma are important agents in veterinary medicine. They have been isolated from patients with non-gonococcal urethritis<sup>16</sup>, Reiter's syndrome, rheumatoid arthritis and lupus erythematosus<sup>17</sup>. However, primary atypical pneumonia remains the only disease of man known to be caused by mycoplasma. Thomas has suggested that since lung tissue antibody appears in patients with primary atypical pneumonia, the possibility that infection with mycoplasma is implicated in conditions characterized by auto-immune serologic reactions requires further investigation<sup>18</sup>. Our finding that red cell antigen I can be altered *in vitro* by mycoplasma when considered with the findings of both mycoplasma<sup>4</sup> and anti-I antibodies<sup>2</sup> in primary atypical pneumonia is an illustration of this concept.

The *in vitro* interference with anti-I agglutination by mycoplasma presents a working hypothesis to explain the inagglutinability by anti-I of red cells of patients with leukaemia. We suggest that although mycoplasma may not be primary agents in human neoplastic disease, they might be opportunist or secondary invaders. They could be involved in combination with another (viral?) agent, as in the mouse hepatitis system<sup>19</sup> or the Rous-helper system<sup>20</sup>.

One other microbial agent is known to alter the I red cell antigen. Marcus<sup>21</sup> found that filtrates of *Clostridium tertium* can destroy the I determinant. These filtrates were specific for I but were more active against the I factor of group A cells than of group O cells. The activity was probably enzymatic. We have found that mycoplasma can alter I antigen reactivity and that they are also more active against the I factor of group A cells than of group O cells. PPLO are enzymatically active, especially in the arginine dehydrolase system<sup>22</sup>, and the *in-vitro* effect we have observed may be due to an enzymatic degradation of the I antigen determinant on normal cells.

We thank Dr. Yokoyama, who prepared the  $\gamma$ -macroglobulin fraction, Drs. J. Fabricant, J. A. Morris, J. Nelson, H. Neimark, J. Seligman and J. Tully, who supplied some of the microbial agents, and D. B. Riggs and M. W. Grabowski for their help.

## LETTERS TO THE EDITOR

## RADIO ASTRONOMY

## Observations of the Quasi-stellar and Other Radio Sources with an Interferometer of Resolving Power 0.4 sec of Arc

OBSERVATIONS made previously at Jodrell Bank with long base-line interferometers<sup>1</sup> have indicated that a small percentage of 384 sources examined with these interferometers have angular sizes of less than 1.0 sec of arc. Six were found to have fringe visibilities ( $\gamma$ ) > 0.8 for transit observations with an east-west base-line of 61,100 wave-lengths.

In order to examine such small sources with an instrument of still higher resolving power, several improvements have now been made to the basic interferometer<sup>2</sup>. The frequency of observation has been changed from 159

Mc/s to 408 Mc/s ( $\lambda = 0.73$  m) and this has enabled low-noise varactor diode parametric amplifiers to be used to greatest advantage. In addition, a transportable and fully steerable 25-ft. diameter radio telescope was constructed for the reception of the radio signals at the outstation, and a slightly more distant site was obtained near Pocklington, Yorkshire, 180,000 wave-lengths (132 km) to the north-east of the 250-ft. diameter *Mark I* radio telescope at Jodrell Bank which was used as the other element of the interferometer.

The transportable alt-azimuth telescope was remotely controlled by radio signals transmitted from Jodrell Bank, and, when it was so desired, an electro-mechanical analogue device at the outstation could steer that telescope to follow automatically any point in the sky, with an accuracy of  $\pm 2^\circ$ . A microwave link was installed to transmit to Jodrell Bank the radio signals received by the

Table 1. QUASI-STELLAR SOURCES

Source and $Z$	Summary of previous interferometric observations with $\lambda = 1.9$ m	Radio observation with tracking interferometer of aerial spacing 180,000 $\lambda$ ( $\lambda = 0.73$ m)	Provisional interpretation of radio measurements

3C 245	$\gamma$ fell to 0.3 at 9,700 $\lambda$	No fringes observed at this base-line	Dimensions $> 12''$
3C 287	$\gamma > 0.8$ at all base-lines except 32,000 $\lambda$ which is based on 1 measurement and may be in error	High $\gamma$ . No variation with H.A.	Not significantly resolved. Dimensions $\leq 0.4''$ . See note 1

See legend to Table 2.

Table 2. SOURCES NOT YET IDENTIFIED (see note 5)

Source	Summary of previous interferometric observations with $\lambda = 1.9$ m	Radio observation with tracking interferometer of aerial spacing 180,000 $\lambda$ ( $\lambda = 0.73$ m)	Provisional interpretation of radio measurements
CTA 21	Not previously studied with high-resolution interferometers	High $\gamma$ . No variation with H.A.	Not significantly resolved. $\leq 0.4''$ . See note 1
CTA 102	Not previously studied with high-resolution interferometers	High $\gamma$ . Not observed at all H.A.s because of poor signal-to-noise ratio	Possibly unresolved. $\leq 0.4''$ . See note 1
3C 119	$\gamma > 0.8$ at all base-lines up to 61,100 $\lambda$	High $\gamma$ . No variation with H.A.	Not significantly resolved. $\leq 0.4''$ . See note 1
3C 138	Not seen previously. See note 3	High $\gamma$ . Small variation with H.A.	Dimensions $\sim 0.5''$
3C 161	$\gamma = 0.1$ at 32,000 $\lambda$ $\gamma = 0.1$ at 61,100 $\lambda$	Small variation of $\gamma$ with H.A.	A component of dimensions $\sim 0.5''$ radiates $\sim 50\%$ of flux at 408 Mc/s. Marked change of intensity with frequency: at 160 Mc/s this component radiates only $\sim 10\%$ of flux
3C 225	$\gamma \sim 0.8$ at all base-lines 2,200 $\lambda$ to 61,100 $\lambda$	Fringes seen at some H.A.s	A component of dimensions $\sim 0.6''$
3C 237	High $\gamma$ out to 61,100 $\lambda$	High $\gamma$ . Variation with H.A.	Possibly double, or elongated
3C 283	$\gamma < 0.1$ at 32,000 $\lambda$ $\gamma = 0.2$ at 61,100 $\lambda$	High $\gamma$ over the restricted range of resolving powers at which it was observable	A component of dimensions $< 0.6''$
3C 298	$\gamma$ fell to 0.6 at 32,000 $\lambda$ 0.1 at 61,100 $\lambda$	Variation of $\gamma$ with H.A.	Possibly double

## Notes to Tables 1 and 2:

(1) The upper limit to the angular dimensions depends on the lower limit of  $\gamma$  and the source model assumed. The value quoted is the maximum diameter (to half-intensity points) that gives  $\gamma \geq 0.7$  for a source with Gaussian brightness distribution when observed with an interferometer of aerial spacing 180,000  $\lambda$ .  $\gamma = 0.7$  allows a generous margin for calibration and measurement errors. It may well be that  $\gamma$  is greater than 0.8 corresponding to dimensions of less than  $0.3''$ .

(2) A source of low flux density which would have given a poor signal-to-noise ratio even if unresolved.

(3) The position of this source as given in the original 3C catalogue<sup>10</sup> is in error by 1 lobe shift. The 408 Mc/s observations were made of the corrected position<sup>11</sup>.

(4) This value of the red-shift, suggested by I. Shklovsky, is not yet generally accepted.

(5) At the Second Texas Conference on Relativistic Astrophysics in December 1964, Dr. Alan Sandage announced that 22 more radio sources had been identified with quasi-stellar objects. Of these, 3 appear in Table 2 (CTA 102, 3C 237 and 3C 298).

Fig. 1. An example of the fringe pattern formed by the source 3C 286 during interferometric observations with radio telescopes 180,000 wave-lengths apart

telescope, and this link was also used, on demand, to relay television pictures of the dials showing the pointing of the remote telescope.

The new instrument was used to examine all sources of adequate flux density at 408 Mc/s which had either given fringes at one of the two longest base-lines used previously or had been tentatively identified with optical objects of quasi-stellar appearance<sup>3,4</sup>. In addition, the sources CTA 21 and CTA 102 were observed, as theoretical estimates indicated that they might have extremely small angular diameters<sup>5,6</sup>. Measurable fringe patterns were observed for approximately half the sources investigated. An example of the fringe pattern formed by the source 3C 286 is shown in Fig. 1.

The results of these observations are summarized in Tables 1 and 2. Table 1 deals with the thirteen sources identified with quasi-stellar objects and Table 2 contains similar data on nine sources for which fringe patterns were observed, but which have not yet been associated with any optical object. The first column of these Tables gives the catalogue number of the source, and, where it is known, the red shift. Previous observations with interferometers of high resolving power are summarized in column 2. Column 3 contains the results of a preliminary analysis of the measurements made with the present base-line. The measurements have been calibrated by assuming that the sources 3C 119, 3C 286, 3C 287 and CTA 21 are unresolved ( $\gamma = 1.0$ ) and this can be justified by means similar to those in the paper of Allen *et al.*<sup>1</sup>. The data in columns 2 and 3 have been combined to give a preliminary interpretation of the angular structure of each source, as shown in the last column.

The only other source for which a measurable fringe pattern was observed at this base-line was 3C 295, which has been identified with the brightest member of a remote cluster of galaxies, with a red shift  $Z = 0.46$ . Fringes of low visibility were observed from this source at some hour angles, with several pronounced minima. These measurements confirm the double structure inferred from observations with a tracking interferometer at a base-line of 61,100  $\lambda$  (ref. 7).

Table 3

Source	Dimensions predicted	Dimensions observed
3C 48	0.4"	$\sim 0.5''$
3C 119	0.3"	$\leq 0.4''$
3C 147	0.2"	$\sim 0.6''$
3C 295	0.6" double	Components $1.7'' \times <1''$
3C 298	0.6"	Possibly double. Components $<1'' \times 1''$
3C 299	0.6"	No fringes observed: source of low flux density with poor S/N
CTA 21	0.01"	$\leq 0.4''$
CTA 102	0.01"	$\leq 0.4''$

Kellermann, Long, Allen and Moran<sup>8</sup> have discussed the correlation between radio sources of very high brightness temperatures and those which showed markedly curved radio spectra<sup>9</sup>. Sligh<sup>5</sup> and Williams<sup>6</sup> have suggested that this may arise because of the long wave-length absorption of radiation by relativistic electrons in the emitting region. They have used the frequency of maximum emission observed for some sources to predict the minimum angular dimensions of the emitting regions of six sources from the 3C catalogue<sup>10</sup>, and of two sources discovered at the California Institute of Technology. At that time the minimum angular dimensions which could be measured were 0.8 sec and the predicted values were all significantly smaller than that.

Table 3 is a revised edition of the table presented by Williams<sup>6</sup> showing in column 2 his predicted dimensions and in column 3 the dimensions deduced from the present observations. The dimensions quoted in column 3 do not necessarily refer to the sizes of the emitting regions of the sources. They may, in fact, refer to the separations of discrete regions of emission in sources of complex structure. Where such complexity is suspected, attempts have been made to estimate the sizes of the components. In all cases the values shown in column 3 may be taken as upper limits to the sizes of the emitting regions.

It will be seen that the measured sizes are now close enough to the dimensions at which synchrotron self-absorption is predicted to occur, to make it very likely that synchrotron self-absorption is in fact responsible for some at least of the observed decrease of flux density at long wave-lengths.

Finally, it may be noted that the unidentified sources in Table 2 and the six sources in Table 1 which gave measurable fringe patterns at this base-line have angular dimensions two orders of magnitude smaller than the values typical of known radio galaxies<sup>11</sup>. Furthermore, of the eleven sources the spectral curvature of which is well established<sup>9</sup> three occur in Table 1 and four occur in Table 2. Two of the remaining four (3C 295, 408) are identified with two of the most energetic radio galaxies known, and two are unidentified. It therefore seems likely that unidentified sources listed in Table 2 are more akin to the small diameter quasi-stellar sources in Table 1 than to less energetic radio galaxies.

We thank Mr. G. K. Miley for help with the observations.

## PHYSICS

A Suggested Mechanism for the 337 $\mu$  CN Maser

STIMULATED emission at a wave-length of 337 $\mu$  has been observed<sup>1</sup> from pulsed discharges in volatile cyanides in the pressure range 0.1–1.0 mm. No other stimulated emission lines from such sources have been observed so far in our experiments. This is a surprising result when we consider how many transitions are possible in a molecular system. In view of the known high dissociation energy of CN it is plausible to assume that either CN or CN<sup>+</sup> is the emitter. We have now recorded the ultra-violet and visible spectra of the discharge using a Hilger large quartz spectrograph. No sign of the band at 3263 Å [ $f'\Sigma \rightarrow a'\Sigma$ ] characteristic of the CN<sup>+</sup> molecule was observed although the 'Melinex' windows of the maser are transparent at this wave-length. In fact all the observed bands belonged to the well-known violet and red systems of CN.

In searching for an assignment experiments were performed using nitrogen fifteen isotopically substituted methyl cyanide. The aim of these experiments was to determine, if possible, the effect of the small mass change on the emitted frequency and hence to deduce which transition was involved. Repeated experiments with the isotopically substituted material failed to give any stimulated emission in conditions where normal CH<sub>3</sub>C<sup>14</sup>N gave strong emission and this despite appropriate adjustments of cavity-length. Thus a small mass change has a drastic effect on the mechanism which leads to stimulated emission.

Since none of the known CN electronic levels is metastable it is most probable that stimulated emission arises from transitions within the ground electronic state. If this were not so, the far infra-red stimulated emission would have to compete with the rapid depopulation by spontaneous emission in the visible and ultra-violet regions. Examination of the known levels in the ground electronic state shows that a transition matching the observed wave-length is to be found between the levels  $K = 8$  and  $K = 7$  in the vibrational state  $v = 2$ . The fact that such specific levels were involved suggests that there is a peculiarity in the rotational energy level structure of CN. Such a phenomenon, namely, rotational perturbation, is very well known, having been first observed by Herzberg<sup>2</sup> in 1929 and further investigated and later explained by other workers<sup>3,4</sup>. Definitive experimental work has been carried out by Broida and Golden<sup>5</sup>, who recorded the emission spectrum of CN at pressures which are of the same order as those used in our experiments.

The electronic spectrum of CN contains two rotational perturbations, one connected with the level  $v = 11$  of the ground state and the other with  $v = 0$  of the second excited state  $B^2\Sigma$ . Both perturbations are due to the first excited state  $A^2\Pi$ , the vibrational levels involved being  $v = 7$  and  $v = 10$  respectively. For the  $v = 0$  level of  $B^2\Sigma$ , the rotational levels  $J = 3\frac{1}{2}(+)$ ,  $7\frac{1}{2}(-)$  and  $15\frac{1}{2}(-)$  are perturbed by the levels  $A^2\Pi_{3/2} J = 3\frac{1}{2}(+)$ ,  $7\frac{1}{2}(-)$  and  $A^2\Pi_{1/2} J = 15\frac{1}{2}(-)$  respectively. The perturbation leads to quantum mechanical mixing of wave functions and displacement of levels, so that transitions from the red system [ $A^2\Pi_{v=10} \rightarrow X^2\Sigma$ ] are allowed with matrix elements appropriate to the violet system [ $B^2\Sigma_{v=0} \rightarrow X^2\Sigma$ ]. Consequently extra lines appear in the violet band systems which involve the  $v = 0$  level of  $B^2\Sigma$ . These extra lines and their companion doublet components are slightly shifted from their expected frequencies and are, at low pressures, more intense than the unperturbed lines. This phenomenon first seen by Herzberg<sup>2</sup> is very clearly shown in the spectra of Broida and Golden<sup>5</sup>. If we now draw the conclusions from Broida and Golden's observations which are appropriate to the stimulated

emission results it will be seen that population of  $v = 2$  of  $X^2\Sigma$  from  $v = 0$  of  $B^2\Sigma$  leads to  $K'' = 8$  having the highest population and  $K'' = 7$  being scarcely populated. This is due, of course, to the usual selection rule  $\Delta K = \pm 1$  and leads to a population inversion.

The failure to observe maser action with C<sup>15</sup>N is now understandable. The conditions for rotational perturbation are stringent since the two levels involved must agree in energy very closely, must have the same angular momentum and the same parity. Thus for C<sup>14</sup>N the two levels at  $J = 7\frac{1}{2}$  of negative parity have energies  $B^2\Sigma = 26,938.8$  and  $A^2\Pi_{3/2} = 26,939.3$  cm<sup>-1</sup>. The energy of the  $B^2\Sigma$  level is mostly electronic (25,751.8 cm<sup>-1</sup>) with only a half quantum of vibrational energy; it is therefore not sensitive to isotopic substitution. However, the energy of the  $v = 10$  level of  $A^2\Pi$  is mostly vibrational (electronic = 9,241.6 cm<sup>-1</sup>, vibrational = 17,631.2 cm<sup>-1</sup>) and is therefore sensitive to isotopic substitution. Thus whereas in the C<sup>14</sup>N molecule we have two levels which agree in energy to within 0.5 cm<sup>-1</sup> the corresponding levels in the isotopically substituted C<sup>15</sup>N differ by 234 cm<sup>-1</sup>. Rotational perturbation is not therefore possible for any of the low vibrational levels of  $B^2\Sigma$  and the maser action is not possible.

## Absorption and Refractive Index Measurements at a Wave-length of 0.34 mm

THE relatively intense, monochromatic source at a wave-length of 0.34 mm which has already been reported<sup>1</sup> has been used to make some measurements of refractive index and absorption coefficient. We are giving here a preliminary account of these measurements, and, at the same time, reporting some progress in our techniques for using the stimulated emission in CN discharges as a laboratory source.

There are three main items of progress. The first is that the length of the discharge tube, given as 9 m in our first publication, has been reduced to as little as 2 m. The second step forward is that we have found it possible to run the source for indefinitely long periods by flowing methyl cyanide vapour through the discharge tube. The rate of flow depends on the pulse repetition rate and is such that the equilibrium pressure is a few tenths of a millimetre. The pressure is fairly critical in a given arrangement and has to be adjusted carefully by varying the flow-rate to obtain maximum radiation intensity. The third result we wish to report in our attempts to make a simpler laboratory source is that we have observed stimulated emission when the breakdown of a condenser by an air spark gap is applied to the tube. Peak voltages as low as 6 kV have been effective, giving peak currents of about 300 amp and a pulse duration of about 1  $\mu$ sec. This condenser spark gap system represents a considerable simplification over the delay line type pulse modulator used in our first experiments.

The measurements we wish to report are of the complex dielectric constant of monohalogen substituted benzenes in the liquid phase. These polar substances were chosen because it had been suggested<sup>2</sup> that their dielectric behaviour could not be described in terms of a single Debye relaxation time, and measurements at sub-millimetre wave-lengths could give strong evidence for or

Table 1

	$n$	$\alpha$ nepers/cm	$\epsilon'$	$\epsilon''$
Fluorobenzene	1.46	21.1	2.11	0.165
Chlorobenzene	1.51	14.5	2.28	0.117
Bromobenzene	1.55	12.1	2.39	0.100
Iodobenzene	1.60	9.1	2.57	0.078

All measurements were made at temperatures between 20° C and 24° C.

against this. The quantities measured were refractive index  $n$  and absorption coefficient  $\alpha$  which are related to the complex dielectric constant  $\epsilon$  with real and imaginary parts  $\epsilon'$  and  $\epsilon''$  thus:

$$\epsilon = \epsilon' - i\epsilon'' = n^2(1 - ik)^2$$

hence:

$$\epsilon' = n^2(1 - k^2) \quad \epsilon'' = 2n^2k$$

where:  $k = \frac{\alpha\lambda_0}{4\pi n}$ ,  $\lambda_0$  measured in vacuum.

A Michelson interferometer was used to determine  $n$  by measuring the change in thickness of liquid path to give successive maxima in fringe intensity. Absorption coefficients were measured by a variable path liquid cell in front of a Golay detector. Results are given in Table 1. The estimated accuracy of these measurements is that values of  $n$  are within 1 per cent and values of  $\alpha$  are within 2 per cent.

Fig. 1. Cole-Cole plots of the dielectric behaviour of the monohalogen substituted benzenes. They are constructed from the data of Poley and the new measurements at 0.34 mm wave-length show significant departures from the semicircular arcs

These results are most easily related to lower frequency observations by the Cole-Cole<sup>3</sup> plots of Fig. 1. The arcs are derived from the data of Poley with his shortest wave-length point ( $\lambda = 8$  mm) given explicitly. It will be seen that in all cases the new 0.34-mm values lie well away from the semi-circular arcs indicating the existence of an absorption process additional to that predicted by the

Debye expression. As Poley pointed out, there was already some evidence for this in the case of iodobenzene from his 8-mm wave-length point not lying on the arc, but the present results show much more clearly that such additional absorption is present in all the monohalogen substituted benzenes.

We thank the Central Electricity Research Laboratory, Leatherhead, for the loan of high-voltage equipment kindly arranged by Mr. J. Looms.

### Stress Relaxation in Solids

THE purpose of this communication is to direct attention to a similarity in the shape of stress-log time graphs relating to static stress relaxation in solid materials. For a number of high polymers and metals the following relation between the inflexion slope  $F$  of the stress-log time curves and the total decrease in stress  $\Delta\sigma$  was found:

$$F \approx 0.1 \Delta\sigma \quad (1)$$

$F$  is defined as  $(d\sigma/d \ln t)_{\text{inflexion}}$ . A condition for the applicability of equation (1) seemed to be absence of internal stresses, that is, careful annealing. The substances investigated were rubber hydrochloride<sup>1</sup>, polyethylene<sup>2,3</sup>, cellulose and paper<sup>4</sup>, polycrystalline and single crystal cadmium, indium, lead and tin<sup>5</sup>, and polycrystalline molybdenum<sup>6</sup>. Experiments have also been carried out on a number of other substances including polyisobutylene, polyvinyl acetate, beryllium, aluminium, Lipowitz's alloy, cetyl alcohol, and single crystals of lithium fluoride<sup>7</sup>.

The conformity of the sigmoid stress-log time curves for solids of different types is illustrated by the examples given in Fig. 1. The approach to stress equilibrium varied appreciably from one solid to another. In cadmium, for example, stress equilibrium could be achieved in a few days, while times of the order of 10 days were needed for lead single crystals; even after this period no equilibrium was observed for polycrystalline samples. Initial transients, apparently not belonging to the main relaxation process represented by equation (1), were observed for tin and gallium at moderate strain rates of  $10^{-3}$ – $10^{-4}$  s<sup>-1</sup>. For other solids, such as cadmium or polyisobutylene, such transients appeared at strain rates of the order of 1 s<sup>-1</sup> corresponding to straining times of the order of 1–10 ms. On separating the transients from the main process agreement with equation (1) was achieved. Deviations from this relation were found for samples of polyethylene containing inhomogeneous internal stresses (insufficient annealing) and for polypropylene and beryllium, both of which were apparently difficult to free from internal stress.

Most experiments were performed at room temperature. Molybdenum was measured at 90° K. At this temperature, the constant of proportionality of equation (1) was only 7 per cent lower than at room temperature. Besides this independence of temperature, the constant of equation (1) was also little dependent on initial stress, the main effect of increasing this being to shift the curves toward shorter times<sup>8,9</sup>. Over the whole range of initial stresses and strain rates covered by the measurements, the coefficient of variation of the constant of proportionality of equation (1) was approximately  $\pm 10$  per cent.

Fig. 1. Stress relaxation curves for some high polymers and metals in the  $(\sigma - \sigma_\infty)/(\sigma_0 - \sigma_\infty)$  (log  $t$ ) representation. Curves  $a, b, c, d, f$ —tension, curve  $e$ —compression.  $a$ , Lead, 99.999 per cent,  $\sigma_0 = 4.0 \times 10^7$  dyn  $\text{cm}^{-2}$ ,  $t_1 = 4.1$  s,  $\dot{\epsilon} = 4.2 \times 10^{-8} \text{ s}^{-1}$ , temperature  $40.7^\circ \text{C}$ ,  $\sigma_\infty/\sigma_0 = 0.15$ ;  $b$ , polyisobutylene, sp. gravity  $0.92 \text{ g cm}^{-3}$ ,  $M \approx 10^5$ ,  $\sigma_0 = 4.0 \times 10^4$  dyn  $\text{cm}^{-2}$ ,  $t_1 = 6.2$  s,  $\dot{\epsilon} = 5.0 \times 10^{-8} \text{ s}^{-1}$ ,  $\sigma_\infty/\sigma_0 \approx 0$ ;  $c$ , cadmium, 99.999 per cent,  $\sigma_0 = 1.3 \times 10^8$  dyn  $\text{cm}^{-2}$ ,  $t_1 = 1.7$  s,  $\dot{\epsilon} = 4.2 \times 10^{-8} \text{ s}^{-1}$ ,  $\sigma_\infty/\sigma_0 = 0.10$ ;  $d$ , polyethylene, sp. gravity  $0.920 \text{ g cm}^{-3}$ , crystallinity 42 per cent,  $\sigma_0 = 1.9 \times 10^8$  dyn  $\text{cm}^{-2}$ ,  $t_1 = 1.7$  s,  $\dot{\epsilon} = 4.2 \times 10^{-8} \text{ s}^{-1}$ ,  $\sigma_\infty/\sigma_0 = 0.39$ ;  $e$ , indium, 99.999 per cent,  $\sigma_0 = 2.0 \times 10^7$  dyn  $\text{cm}^{-2}$ ,  $t_1 = 6.2$  s,  $\dot{\epsilon} = 1.2 \times 10^{-8} \text{ s}^{-1}$ ,  $\sigma_\infty/\sigma_0 \approx 0$ ;  $f$ , rubber hydrochloride, sp. gravity  $1.12 \text{ g cm}^{-3}$ ,  $M = 2.4 \times 10^5$ ,  $\sigma_0 = 1.1 \times 10^7$  dyn  $\text{cm}^{-2}$ ,  $t_1 = 2$  ms,  $\dot{\epsilon} = 2.5 \text{ s}^{-1}$ ,  $\sigma_\infty/\sigma_0 = 0.32$ .  $\sigma_0$ , Initial (peak) stress;  $\sigma_\infty$ , equilibrium stress;  $t_1$ , straining time;  $\dot{\epsilon}$ , strain rate

The curve shape exemplified in Fig. 1 is usually explained either by assuming a spectrum of relaxation times or an activation energy that decreases (linearly) with stress. The activation concept based on a single Boltzmann term with a stress-dependent energy of activation gives, formally, a close agreement with the observed curve shape. The basic relation between the rate of stress decrease with time and stress is:

$$d\sigma/dt \sim \exp(\sigma/F) \quad (2)$$

with:

$$F = kT/v \quad (3)$$

$v$  is volume of activation. Here  $F$  is nearly identical with the inflexion slope of  $\sigma$  (ln  $t$ ). Considering the simple case of complete stress dissipation, as in cadmium or polyisobutylene, where  $\Delta\sigma$  is equal to the initial (maximum) stress,  $\sigma_0$ , the relation  $v\sigma_0 \approx 10 kT$  is obtained from equations (1) and (3). Relations between  $d\sigma/dt$  and  $\sigma$  of the type  $d\sigma/dt \sim \sigma \exp(\sigma/F)$ , which also closely represent the observed curve shape, give  $v\sigma_0 \approx 8 kT$ . The difficulty in finding a reasonable explanation of this in terms of equation (2) is underlined by the independence of  $F/\sigma_0$  (or  $F/\Delta\sigma$ ) of temperature<sup>10,11</sup>. Despite modifications of the basic theory, difficulties of this kind seem to persist.

Fig. 2. Illustration of the stability of the ratio  $F/\Delta\sigma$ . The line at  $F/\Delta\sigma = 0.37$ , that is,  $1/e$  corresponds to Maxwellian relaxation. The histogram is based on 320 measurements tabulated in the previous papers (refs. 1-6) together with 75 unpublished  $F/\Delta\sigma$  values

Besides stress activation, pronounced spectral effects were observed in the present investigation—for example, in experiments in which the straining time was varied. Formally, the results could be interpreted in terms of a spectrum of relaxation times, which shifts along the log time axis when temperature or initial stress is changed. The extent of this shift and the original position of the spectrum are dependent on the characteristics of the material. The influence of stress is most pronounced in metals. It is less distinct in semicrystalline polymers and, at low deformations, apparently absent in polymers of the amorphous type. The shape of the spectrum is, however, largely independent of structure and composition. When approximated by a box distribution it extends over 4.3 decades of time.

Another illustration of the validity of equation (1) is the frequency distribution, shown in Fig. 2, and relating to relaxation results obtained with both polymers and metals. The mean of  $F/\Delta\sigma$  is  $0.10 \pm 0.01$ . Support for the validity of equation (1) is found in a number of reports (see refs. 1-6). Most have been concerned, however, with limited time intervals and with sub-

stances for which the main inflexion region of the  $\sigma$ (log  $t$ ) curves is not covered by the period of measurement, as is the case with steel.

This investigation was supported in part by the Swedish Technical Research Council.

## GEOPHYSICS

### Determination of the Density of Air at an Altitude of 3,500 km

In 1963 an investigation was begun of densities of air at heights above 3,000 km. Observations were started in January 1964 on the high *Midas* satellites (*Agena* satellites in near-polar orbits at heights mainly between 3,000 and 4,000 km) with a special camera at the prime focus of the 24-in.,  $f/5$  reflector of the University of London Observatory. A tilting mirror gives timed breaks in both satellite and star trails and the precision has been found to be about 1" in position and 5 msec in time. The *Midas* objects are well recorded to magnitude 9, at angular velocities at 300"/sec, using special film (SO 118) obtained from Eastman Kodak and processed to give a speed of 2,000 A.S.A. A typical frame is shown in Fig. 1. In work recorded here observations were made at selected positions on high passes to maximize the accuracy in determining the satellite latitude, and hence mean anomaly. To derive the mean anomaly from each observation approximate orbit elements were obtained from various sources, including *Norad* (via the Goddard Space Flight Center) and the Smithsonian Astrophysical

Observatory. Near-zenith observations were also used to derive accurate positions for the ascending node and its motion.

In early 1964 it was learned that the object 1963 30D (magnitude 8) that originated from the 1963 30A launch (*Agna D*) was an inflated balloon satellite—an experiment by the Lincoln Laboratories, of the Massachusetts Institute of Technology. Correspondence with the Smithsonian Astrophysical Observatory and with the Lincoln Laboratories produced information on the size of the balloon (2.4 m diam. nominal) and its mass (1.25 kg). Consequently its area/mass ratio is some 1,000 times greater than the ratio for the parent *Agna* vehicle and observations were therefore concentrated on 1963 30D. It has been possible to determine the change in orbital period due to air drag much earlier than was expected from the original programme and a determination of the air density at 3,500 km has been obtained. This altitude is greatly in excess of those so far surveyed, the greatest previously being about 1,500 km<sup>1</sup>.

One obstacle in extending measures of orbital period changes to great altitudes is the large competing perturbation due to solar radiation pressure. Many investigations have been made of these perturbations, for example by Musen<sup>2</sup>, and a point of importance is the absence of any perturbation in the anomalistic period when the whole orbit is in sunlight<sup>3</sup>. For the *Midas* objects the sunlit periods may exceed ten weeks.

Observations on 1963 30D were made in two series. Series I covered the period April 26–July 2, with the orbit precessing into full sunlight on about June 11. Series II covered the morning passes first accessible on August 26 and continued until October 8, with the orbit again including shadow on about September 11.

To derive an orbital period which represents the orbital energy it is necessary to remove the motion of perigee, which is very non-uniform even during the sunlit periods, due to solar radiation pressure. Therefore the derived

Fig. 1. Part of a frame obtained on September 23, 1964, showing the trail of satellite 1963 30D with a timing break lasting about 2 sec, and the star trails with the corresponding breaks. The reproduced part of the satellite trails is about 0.5° in length

Fig. 2. The residuals in mean anomaly in units of revolutions, from a least-squares fit of mean anomaly to a linear function of time with the data in Series I. The date is the Modified Julian Date (MJD) and the arrow indicates June 11 when the orbit moved into fullsunlight. The points at MJD 534 and 550 indicate a nearly constant orbital period followed by a sharp change before the solar radiation pressure perturbation is removed on June 11. Results received from the Smithsonian Astrophysical Observatory confirm this curious behaviour, at present unexplained

anomalistic mean motions were modified by subtracting the mean motion of perigee used in each analysis, a procedure also followed by Zadunaisky *et al.* in their investigations of *Echo I*<sup>4</sup>.

The orbit elements used limited the accuracy to which the anomalistic period could be obtained from the observations; in particular, uncertainty in the argument of perigee introduced the largest errors into the anomalistic period—about one part in 10<sup>3</sup>, for the orbital eccentricity of 0.04.

Fig. 2 shows a plot of the residuals in mean anomaly from a least squares fit to a linear function of time to the data in Series I. The strong curvature in the left-hand part reflects the acceleration due to solar radiation pressure, about  $-1 \times 10^{-8}$  period/period. After June 11 the orbit is entirely in sunlight and the orbital period is essentially constant.

Series I gave a modified anomalistic period of 0.116 622 35 days for the date June 21.442; Series II 0.116 620 34 days for August 31.674. The rate of change of period was therefore  $-2.82 \times 10^{-8}$  period/period, and is estimated to be accurate to 10 per cent. There is no contribution by solar radiation pressure to this value, so it represents the effect of air drag only.

Using the air density relation given by King-Hele and Walker<sup>5</sup>, the following expression is obtained:

$$A/m \cdot C_D \cdot \rho^* = 3.02 \times 10^{-18} \text{ gm/cm}^3$$

$\rho^*$  is the air density at a height above perigee of one-half the scale height (assumed here 500 km);

$A/m$  is the area/mass ratio in cm<sup>2</sup>/g;

$C_D$  is the drag coefficient.

Recent brightness fluctuations suggest that 1963 30D is no longer fully inflated. Discussion with D. E. Smith (Radio Research Station, Slough) suggests that  $A/m$  may be only about 30, from investigations of the effect of solar radiation pressure on the orbital eccentricity. Furthermore, correspondence with Dr. I. Shapiro at the Lincoln Laboratories also indicates that the balloon is no longer spherical. A value of 30, which seems unlikely to be in error by more than 20 per cent, was adopted.

The value of  $C_D$  is debatable but seems likely to lie between 3 and 5 (ref. 6); the uncertainty in  $C_D$  at present limits the air density accuracy, but we may take 4.0 as a nominal value, representing the situation where the velocity of the satellite is of the same order of magnitude as the most probable molecular velocity and where the reflexion of the molecules from the satellite surface is primarily diffuse and not specular. Then the density is  $2.5 \times 10^{-20}$  g/cm<sup>3</sup> at 3,500 km. This result does not disagree with figures extrapolated over about three scale heights from models by Nicolet<sup>6</sup>. It should be stressed that the density is an average value over two months and refers approximately to the sunrise and sunset regions, excluding the diurnal bulge.

I thank Prof. C. W. Allen of the University of London Observatory for permission to use the 24-in. reflector during this work.

## GEOCHEMISTRY

### Increasing the Settling Rate of Flocculated Suspensions

THERE is a wide range of fields in which sonic, ultra-sonic or pulsatory techniques have been found to improve the performance of a transfer process. In liquid-liquid extraction processes, for example, the effect of pulsation has been shown to increase the capacity of a unit by as much as 200 per cent<sup>1-3</sup>. Mass transfer rates and the coefficient of heat transfer are also claimed to be improved by sonic vibrations<sup>4-6</sup>.

These results suggest that vibrations might improve the performance of other processes. It is well known, for example, that the sedimentation rate of fine particles suspended in liquids can often be increased by the addition of a flocculating agent but, so far as we are aware, the influence of vibration on the settling rate of such suspensions has not been explored.

As part of a general programme dealing with the rheology of suspensions the effects of mechanical vibration at 50 c.p.s. on the settling rate of aqueous suspensions of polyvinyl chloride spheres (possessing a maximum diameter of 1 micron) and a kaolin china clay are being examined. When these are flocculated with potassium alum solution they develop definite yield stresses. The sedimentation

tests are carried out in cylindrical tubes of 3 cm internal diameter and 60 cm in height, under static and vibrated conditions. Typical results for polyvinyl chloride spheres at a volume concentration of 15.8 per cent and for kaolin at a volume concentration of 3.5 per cent are shown in Fig. 1. The differences in the sedimentation curves are quite pronounced, showing increases in the settling rate, with the vibration, of at least 200 per cent.

Although longitudinal and transverse vibrations both give improved settling rates compared with static conditions, it appears that the greatest improvement is obtained with transverse vibrations. Amplitude variations have very significant effects, particularly in the initial stages of settling, and the tube diameter may in some cases be important. The mechanism involved is at present under investigation and a more detailed report of the work will be published in the near future.

## MINERALOGY

### Interlamellar Sorption in a 'Methylated' Montmorillonite

As a sequel to the work already carried out on interlamellar sorption of organic molecules on methylated graphitic acid<sup>1</sup> and on the structure of methylated graphitic acid by electron diffraction<sup>2</sup>, I decided to try to methylate montmorillonite, and to examine its capacity for interlamellar sorption. The problem of methylating montmorillonite has been discussed a good deal, and many arguments for and against have been put forward, and have been linked with the two structural models for montmorillonite.

A Wyoming montmorillonite was used in this work. It was acidified by the method described by Girod and Lacroix<sup>3</sup>.

The H<sup>+</sup> montmorillonite, once prepared, was dried at 110° C for 12 h and methylated, following Vogel's method<sup>4</sup>. The methylated product was washed several times with ether, then dried *in vacuo* in a desiccator with P<sub>2</sub>O<sub>5</sub>.

The basal spacing obtained was 12.35 Å, and remained constant after treatment with numerous organic substances, both polar (amines, alcohols, water) and non-polar (paraffins, toluene).

However, on heating the methylated sample in a capillary to 110° C and 130° C for 48 h, the layers become disordered, and the basal spacing diminishes by 1 Å (the disorder is indicated by a spreading of the basal spacing reflexion). These heated samples recover the basal spacing if treated with octylamine, but no higher spacing than 12.35 Å appears.

It is to be noted that original montmorillonite gives high spacings with aliphatic amines, in accordance with the observations of Aragón, Cano-Ruiz and MacEwan<sup>5</sup>, and Armin Weiss<sup>6</sup>. After 'methylation', the montmorillonite fails to react. This result does not agree with those of Brown, Greene-Kelly and Norrish<sup>7</sup>, or that of Greenland and Russell<sup>8</sup>. Methylation was carried out until no reaction of the diazomethane with the clay was observed<sup>9</sup>, only a slight bubbling corresponding to the diazomethane itself—in contrast to the intense bubbling of the first days.

Fig. 1. Sedimentation under static and vibrated conditions. *a*, Polyvinyl chloride spheres; *b*, kaolin.

If the water contained between the sheets of the montmorillonite reacts with the diazomethane, or with the methyl group, to hydrolyse them, giving methanol as a final product, the addition of an excess of diazomethane would result in eliminating the interlamellar water, and finally the diazomethane would react with the clay.

If any methanol remained between the layers it would be displaced by the long-chain aliphatic amines with which the clay was treated, giving large spacings, especially after heating to 110° C.

While in G. F. Walker's laboratory in Melbourne, I investigated the sorption of aliphatic amines by a montmorillonite containing amorphous carbon between the sheets, resulting from the decomposition of sorbed glycerol, and the basal spacings obtained were similar to those given by normal montmorillonite. The polymerization of the diazomethane, as suggested by Vivaldi and Hendricks<sup>9</sup> and by Greenland and Russell<sup>8</sup>, is more acceptable as an explanation, but might not be adequate to explain the diminution of the spacing after treatment at 110° C, and the increase to the original value on sorbing an amine. I suspect methylation of the clay. This conclusion is supported by the experiments of Barrer and Realy<sup>10</sup> with a phenylmontmorillonite prepared by Deuel.

I thank Dr. D. M. C. MacEwan for his advice.

## CHEMISTRY

### Homogeneous Electron Exchange Reactions of Aromatic Molecules

RECENT reviews summarize the large body of information available on the rates and mechanisms of inorganic electron exchange processes<sup>1-3</sup>. In contrast, purely organic systems have received minor attention. The homogeneous electron exchange rates ( $k_{\text{exc}}$ ) for a few aromatic hydrocarbons and other individual systems have been measured<sup>4,5</sup>. We have been interested in the values of  $k_{\text{exc}}$  for aromatic molecules containing polar functional groups and particularly the effect of solvents, substituents, and molecular geometry on these rates. We wish to report some preliminary results which show that we are able to measure  $k_{\text{exc}}$  with a precision which is capable of detecting subtle differences due to molecular structure and environment.

The measurement of  $k_{\text{exc}}$  for the electron transfer process  $X^- + X \rightleftharpoons X + X^-$  can be measured via electron paramagnetic resonance if the species  $X^-$  is the paramagnetic radical ion  $X^{\cdot-}$ . The theory of the electron paramagnetic resonance exchange phenomenon is not particularly simple but the bimolecular rate constant  $k_{\text{exc}}$  is obtained fairly easily by measuring the broadening of hyperfine lines in the electron paramagnetic resonance spectrum of  $X^{\cdot-}$  as a function of concentration of the parent compound,  $X$  (refs. 4-6). All the radical ions involved in the work recorded here were generated via controlled

Table 1. VALUES OF  $k_{\text{exc}}$  FOR SELECTED AROMATIC ELECTRON EXCHANGE SYSTEMS

‡ Bimolecular rate constant in l. mole<sup>-1</sup> sec<sup>-1</sup>.

§ *N,N*-dimethylformamide.

potential electrolysis. Details of the experimental techniques will be published soon.

Table 1 summarizes some of the systems examined. The unsubstituted aromatic hydrocarbons like A/A<sup>-</sup> (see legend to Table 1 for explanation of abbreviations) show very rapid exchange rates. (The naphthalene/naphthalide ion exchange measured by Ward and Weissman has  $k_{\text{exc}} = 10^8$ – $10^9$  l. mole<sup>-1</sup> sec<sup>-1</sup>) (ref. 6). Some substituted aromatics like Q/Q<sup>-</sup> also are quite rapid. However, when a strong electron acceptor function like the nitro group is present, the value of  $k_{\text{exc}}$  decreases by about a factor of 10. It is known from the electron paramagnetic resonance hyperfine coupling constants that the unpaired electron density in NB<sup>-</sup> is strongly localized in the nitro group ( $a_N$  = about 10 g) (ref. 7). In *p*- and *m*-dinitrobenzene anions, the <sup>14</sup>N coupling constants are considerably smaller than in NB<sup>-</sup> (the two <sup>14</sup>N coupling constants are equivalent in each anion radical and for *p*-DNB<sup>-</sup>  $a_N$  = 1.7 g; for *m*-DNB<sup>-</sup>  $a_N$  = 4.7 g) (ref. 8). Hence it was reasoned that  $k_{\text{exc}}$  for these systems should be faster than for NB/NB<sup>-</sup>. This prediction is well illustrated by the results in Table 1. Furthermore, it appears that other substituent groups which decrease  $a_N$  in a mono-nitro compound tend to increase the value of  $k_{\text{exc}}$  above that of NB/NB<sup>-</sup>. This is illustrated by the value for the system 3,5-dichloronitrobenzene and its anion radical, where  $a_N$  = 7.6 g. We are investigating the realities of these structural effects in far more detail. The importance of the results presented here is that it establishes clearly that such investigations can be made reliably.

The most striking effect in Table 1 is the dependence of  $k_{\text{exc}}$  on the solvent system. Addition of 10 per cent water to the DMF decreases the exchange rate for Q/Q<sup>-</sup> slightly. This same alteration causes  $k_{\text{exc}}$  to decrease by a factor of 100 in the case of NB/NB<sup>-</sup>. Electron paramagnetic resonance investigations have established strong solvation of NB<sup>-</sup> (refs. 9–12), and this preferential hydrogen-bonding or solvation of the anion radical represents an energy barrier to the exchange process and an expected decrease in  $k_{\text{exc}}$ . Strong solvent effects on the exchange rate of fluoranil and its semiquinone have been observed by Calvin *et al.*<sup>13</sup>.

The reliability of the present results is demonstrated by measurements of  $k_{\text{exc}}$  for Q/Q<sup>-</sup>. This rate was measured at the University of Kansas and at the Varian Research Laboratories in Zürich using entirely different solvents, compounds and experimental methods (the latter investigation used a flow system). Although the precision of the flow measurements was poorer,  $k_{\text{exc}}$  was found to be  $3.7 \pm 1 \times 10^8$  to be compared to  $3.8 \pm 0.2 \times 10^8$  given in Table 1.

We are now attempting to determine if the variation in rates is due primarily to differences of anion solvation

or unpaired electron distribution in these systems. The investigation is being extended to molecules of interest in biological electron transport processes.

### Structures of some Mercury(II) Complexes

1,6-DITHIACYCLODECA-*cis*-3, *cis*-8-diene<sup>1</sup> forms a *bis*-(mercuric chloride) adduct. The obvious postulate for the structure of this complex is shown in diagram I, with each mercury atom in three-fold co-ordination. The actual crystal structure determined by X-ray analysis, however, is of the polymeric type (diagram II), with one mercury atom, Hg(2), in tetrahedral co-ordination and the other, Hg(1), in an only slightly distorted mercuric chloride molecule. The Hg(2)-S and Hg(2)-Cl distances are 2.53 and 2.51 Å, respectively. The complex crystallizes in the monoclinic system, space group  $P2_1/m$ , with two molecules

of  $C_8H_{12}S_2Hg_2Cl_4$  in a cell of dimensions  $a = 7.29$ ,  $b = 17.01$ ,  $c = 6.20$  Å,  $\beta = 92^\circ 43'$ . The structure was solved by Patterson and Fourier methods and refined by least-squares calculations; the final value of the discrepancy  $R$  over 1,158 independent reflexions is 13.6 per cent.

The zinc atom in dichlorobis(thiourea)zinc is tetrahedrally co-ordinated<sup>2</sup>. The analogous mercury compound does not have the same type of structure but contains planar  $(N_2H_4CS)_2ClHg^+$  cations ( $C_{2v}$  symmetry) and  $Cl^-$  anions. The unit cell is orthorhombic, space group  $Pmnm$ , contains two 'molecules' of  $(N_2H_4CS)_2HgCl_2$ , and has dimensions  $a = 12.79$ ,  $b = 5.89$ ,  $c = 6.44$  Å. The structure was elucidated by Patterson and Fourier methods and refined by least-squares calculations. The value of  $R$  over 444 independent reflexions is 18.3 per cent. The dimensions of the  $(N_2H_4CS)_2ClHg^+$  cation are Hg-S 2.37 Å, Hg-Cl 2.56 Å,  $\angle SHgS$   $128^\circ 45'$ ,  $\angle SHgCl$   $110^\circ 37'$ .

In so far as the hybridization concept is a valid description of the covalent contribution to the bonding in metal complexes (compare with Jørgensen<sup>3</sup>) the valency angles in the thiourea complex can be interpreted to imply that the mercury ( $s, p$ )-hybrid orbitals directed towards the sulphur atoms have 38 per cent  $s$ -character and the orbital directed towards the chlorine atom 23 per cent  $s$ -character; these estimates are in good accord with the bond lengths, the Hg-Cl distance being slightly longer than that appropriate to  $sp^3$ -bonding (2.51 Å). In dichlorobis(thiourea)zinc the valency angles  $SZnS$  and  $ClZnCl$  are  $111.5^\circ$  and  $107.3^\circ$ , respectively, implying that here also the orbitals directed towards the sulphur atoms have more  $s$ -character (27 per cent) than the orbitals directed towards the chlorine atoms (23 per cent), though the difference is not so great as in the mercury compound. These results can be ascribed to a relationship between hybridization and electron-donor capacities of ligands<sup>4</sup>; orbitals directed towards the least electronegative ligands have more  $s$ -character than those directed towards the more electronegative ligands. That the variation of  $s$ -character with ligand electron-donor ability is much more pronounced for mercury orbitals than for zinc orbitals is a clear reflexion of the greater  $s-p$  energy separation in mercury.

The co-ordination number of mercury in these complexes increases from three to four with concomitant lengthening of the Hg-S bond when thiourea is substituted by 1,6-dithiacyclodeca-*cis*-3, *cis*-8-diene, a sulphur ligand of poorer electron-donor ability. The co-ordination number increases and the Hg-S bond lengthens (and weakens) further when a sulphur-containing ligand of still poorer electron-donor ability is used. X-ray analysis of the coloured complex dichlorobis(phenoxathiin)mercury reveals a crystal structure not unlike that of dichlorobis(pyridine)mercury<sup>5</sup>, and containing infinite chains (diagram III). The complex crystallizes in the monoclinic system, space group

B2/b, with four molecules of  $C_{24}H_{16}O_2S_2HgCl_2$  in a cell of dimensions  $a = 31.00$ ,  $b = 19.46$ ,  $c = 3.95$  Å,  $\gamma = 111^\circ 18'$ . The mercury atom has two short collinear bonds to chlorine atoms (that is, a discrete mercuric chloride molecule can be recognized) while two further chlorine atoms and two sulphur atoms at greater distances complete an octahedral co-ordination. The Hg-S bond is very long ( $\sim 3.0$  Å) and undoubtedly very weak and thus differs qualitatively from the more conventional 'covalent/ionic' Hg-S bonds in the complexes described above. The complex readily dissociates and the crystals at room temperature and exposed to the atmosphere lose their phenoxathiin content in a few days. A plausible description of the Hg-S bonding is that it is of the relatively weak charge-transfer type<sup>6</sup>, for the lower ionization potential of sulphur relative to oxygen then accounts for the sulphur being the atom involved in the mercury-ligand bond; a description of the complex based on purely electrostatic attraction, on the other hand, would naturally favour the oxygen atom for bonding.

## Catalytic Activity of Haemin on the Decomposition of Hydrogen Peroxide

It is known that the velocity of decomposition of  $H_2O_2$  increases in the ratio  $1 : 10^3 : 10^{10}$  if one uses  $Fe^{3+}$  ion, haemin or catalase as a catalyst<sup>1</sup>. There have been several attempts to construct a general mechanism for these reactions<sup>2-4</sup>. The theory of Jones and Wynne-Jones seems to offer satisfactory explanation for many experimental facts<sup>4</sup>. However, there is still need for more experimental evidence to test this theory.

Some light might be shed on this problem by an examination of the haemin-catalysed reaction, since haemin stands, structurally, between a simple  $Fe^{3+}$  ion and a catalase molecule.

The investigation of the haemin-catalysed decomposition of  $H_2O_2$  is complicated by the fact that the catalyst is destroyed by the substrate  $H_2O_2$ . Thus true catalysis by haemin is observed only in the initial part of the reaction. Euler and Josephson found that the  $-(d[H_2O_2]/dt)_{\text{initial}}$  versus  $[H_2O_2]_{\text{initial}}$  graphs had the form of a saturation curve<sup>5</sup>. This fact indicates the formation and subsequent decomposition of a catalyst-substrate complex between haemin and  $H_2O_2$ , although no concurrent change in the visible spectrum of haemin has been observed in an aqueous solution.

From Euler and Josephson's results the dissociation constant of the complex ( $K_M$ ) and the rate constant of its irreversible decomposition ( $k_3$ ) can be obtained. Data taken from their Tables 8, 9 and 10 are plotted in Fig. 1 according to the method of Lineweaver and Burk<sup>6</sup>. For the calculation of  $-(d[H_2O_2]/dt)_{\text{initial}}$  only the first two points of each experiment were used.

From the results shown in Fig. 1,  $k_3 = 2.1 \pm 0.1 \text{ min}^{-1}$  and  $K_M = (8.3 \pm 1.2) \times 10^{-3} \text{ M}$  at  $0^\circ \text{C}$  and  $pH=7$  were

Fig. 1. Lineweaver-Burk plots for the haemin-catalysed decomposition of  $H_2O_2$ .

I,  $[E]_0 = 0.7 \times 10^{-3} \text{ M}$   $pH=7.0$

II,  $[E]_0 = 1.3 \times 10^{-3} \text{ M}$   $t=0^\circ \text{C}$

III,  $[E]_0 = 2.6 \times 10^{-3} \text{ M}$

Data of Euler and Josephson (ref. 5)

obtained. In calculating  $k_3$  the intercept was made equal to  $1/(2k_3[E]_0)$ , on the assumption that two molecules of  $H_2O_2$  are decomposed on the decomposition of each molecule of the complex<sup>7</sup>.  $[E]_0$  is the total concentration of the catalyst. Euler and Josephson's own estimate for  $K_M$  was  $(7.8 \pm 0.4) \times 10^{-3} \text{ M}$ . They used the direct plot of  $-(d[H_2O_2]/dt)_{\text{initial}}$  versus  $[H_2O_2]_{\text{initial}}$ , but this method, owing to the difficulty of estimating  $-(d[H_2O_2]/dt)_{\text{initial}}$  at  $[H_2O_2]_{\text{initial}} = \infty$ , is unreliable.

We can compare the value of  $k_3$  to that of an analogous rate constant in the  $Fe^{3+}$  ion catalysed decomposition. This latter reaction has been shown to proceed also by the formation and subsequent decomposition of a catalyst-substrate complex ( $Fe^{3+}HO_2^-$ )<sup>7-9</sup>. The rate constant for the irreversible decomposition of the complex (also denoted as  $k_3$ ) could not be obtained directly, but a related quantity  $k_3/(\epsilon_I - \epsilon_{Fe}) = 8.1 \times 10^{-2} \text{ M cm min}^{-1}$  at  $27^\circ \text{C}$  was calculated.  $\epsilon_I$  and  $\epsilon_{Fe}$  are the molar extinction coefficients of  $Fe^{3+}HO_2^-$  and  $Fe^{3+}$  at  $440 \text{ m}\mu$ . This value, thus  $k_3$ , was independent of  $pH$  (ref. 8).

In order to calculate  $k_3$ , an independent knowledge of  $\epsilon_I - \epsilon_{Fe}$  is needed. Using the value  $450 \text{ M}^{-1} \text{ cm}^{-1}$  of Evans *et al.* at  $440 \text{ m}\mu$ ,  $k_3 = 36.4 \text{ min}^{-1}$  is obtained at  $27^\circ \text{C}$  (ref. 10). The energy of activation of step 3 is  $16.8 \text{ kcal}$ . It was calculated from the temperature dependence of  $k_3/(\epsilon_I - \epsilon_{Fe})$ , assuming that  $\epsilon_I - \epsilon_{Fe}$  is independent of temperature. Thus  $k_3$  at  $0^\circ \text{C}$  becomes  $2.2 \text{ min}^{-1}$ , independent of  $pH$ .

Using an alternative estimate of Jones *et al.* of  $k_3 = 10 \text{ min}^{-1}$  at  $25^\circ \text{C}$ , we obtain  $k_3 = 0.8 \text{ min}^{-1}$  at  $0^\circ \text{C}$  (ref. 11). The close agreement of  $k_3$  for haemin and  $Fe^{3+}$  ion is

striking. The overall rate constants differ by a factor of several hundred.

Although a detailed comparison of the ferric ion and haemin-catalysed reaction is not possible on the basis of experimental data at present available, nevertheless it seems probable that in both cases in step 3 a breaking of the O—O bond in a co-ordinated  $H_2O_2$  molecule occurs. This process is assisted by the formation of new bonds between the catalyst and one of the oxygen atoms of peroxide, after the O—O bond is broken<sup>9</sup>.

$\pi$  molecular orbitals between  $Fe^{3+}$  and O are of particular interest since they can be formed only after the peroxide bond is broken. (A strong metal-oxygen bond involving one  $\sigma$  and two  $\pi$  molecular orbitals has been shown to occur in  $VO^{2+}$  (ref. 12).)

$H_2O$  ligands in aqueous  $Fe^{3+}$  are not involved in  $\pi$  bonding to the central atom. Similarly, there is negligible  $\pi$  bonding between iron and the nitrogen atoms of porphyrin in haemin<sup>13</sup>. Therefore, the  $Fe^{3+}$ —O  $\pi$  m.o.s in both cases are, in a good approximation, independent of other existing bonds in the molecule. As a consequence the energetic requirement for breaking the O—O bond both in the haemin and  $Fe^{3+}$  ion complexes may be very similar.

The incorporation of haemin in a catalase molecule increases  $k_3$  drastically. According to Jones and Wynne-Jones,  $k_3$  for catalase is  $5.5 \times 10^6 \text{ min}^{-1}$  at  $20^\circ \text{C}$  (ref. 4). This phenomenon seems to present one of the most interesting problems of catalase kinetics.

### Free Radical Sources based on Zero-valent Metal Derivatives

We have previously shown that systems containing metal carbonyls<sup>1</sup>, particularly those in which the metal is in the zero oxidation state, and suitable organic halides, are sources of free radicals, as evidenced by their ability to initiate vinyl polymerization in the homogeneous liquid phase. It seemed of interest to extend these observations to other derivatives of zero-valent metals, especially those having more easily removable ligands than carbon monoxide, since under these conditions free radical formation would be expected to occur more readily. We report here investigations with two such derivatives—the hexaphenylisocyno derivatives of molybdenum (0) and tungsten (0).

As a ligand, phenyl isocyanide resembles carbon monoxide, except that the extent of back-donation from the  $d$  orbitals of the metal to the ligand is less important; thus the double-bond character of the metal-carbon bond is reduced, and the ligand is less firmly held.

The hexaphenylisocyno derivatives were prepared by reduction of the appropriate metal compounds in anhydrous ethanol in the presence of phenyl isocyanide, according to the methods of Malatesta and Sacco<sup>2</sup>, and afterwards purified as described by these authors. Molybdenum trioxide was reduced by hydrazine hydrate and tungsten hexachloride by magnesium powder and acetic acid.

Neither derivative alone is an initiator of the polymerization of methyl methacrylate, but both initiate it readily in the presence of a low concentration of a suitable organic halide such as carbon tetrachloride. The variation of the rate of polymerization with increasing  $[CCl_4]$  is remarkably similar to that observed with the metal carbonyls<sup>1</sup>, increasing rapidly at first and finally becoming almost independent of  $[CCl_4]$  for values of the latter exceeding about  $0.1 \text{ mole l}^{-1}$ .

The kinetics of these reactions (in inactive light) are somewhat more complicated than those generally found with metal carbonyls, especially with the tungsten derivative, since the rate of initiation decreases with time from its initial value to a greater extent than corresponds to any simple order of reaction. The mean rates of polymerization of methyl methacrylate  $\bar{w}$  (effectively in bulk) over 30 min at  $80^\circ \text{C}$  are given by:

$$\bar{w} = 1.9 \times 10^{-2} [Mo(CNPh)_6]^{1/2} \text{ mole l}^{-1}\text{s}^{-1} \quad (a)$$

$$\bar{w} = 1.5 \times 10^{-2} [W(CNPh)_6]^{1/2} \text{ mole l}^{-1}\text{s}^{-1} \quad (b)$$

for 'high'  $[CCl_4]$ . The overall activation energies are comparatively low—in the range 11–15 kcal mole<sup>-1</sup>—and polymerization may be readily initiated at room temperature. The free radical nature of the reaction is indicated by the half-order in the initiator concentration, and the 'normal' value for the ratio  $k_p k_t^{-1/2}$  calculated from mean rates and degrees of polymerization ( $k_p$ ,  $k_t$  are the velocity coefficients of propagation and termination, respectively).

Hexaphenylisocyno tungsten (0) does not show the 'inhibitory' features which are so marked with tungsten carbonyl<sup>3</sup> so that the relation (1b) is obeyed over the whole range of concentrations investigated (up to  $1.2 \times 10^{-3} \text{ mole l}^{-1}$ ). The molybdenum derivative inhibits the reaction at higher concentrations similarly to  $Mo(CO)_6$  so that (1a) holds only for  $[Mo(CNPh)_6] < 5 \times 10^{-4} \text{ mole l}^{-1}$ , approximately.

These systems are considerably more active initiators than those incorporating the corresponding metal carbonyls. Thus the mean rates given by reaction (1) are greater than the initial rates for the carbonyls; this is very marked with the tungsten compounds, the difference amounting to a factor of nearly 3, or about 8 in the rate of initiation. These results, therefore, are completely consistent with the view that phenyl isocyanide is a more easily displaceable ligand. At concentrations of metal derivative exceeding about  $10^{-3} \text{ mole l}^{-1}$  the differences in rate with the two types of ligand are even greater on account of inhibition in the carbonyl systems.

Addition of phenyl isocyanide ( $9 \times 10^{-4} \text{ mole l}^{-1}$ ) to reactions initiated by the tungsten derivative reduces the rate of polymerization at  $80^\circ \text{C}$ , but to an extent not much in excess of that observed in free-radical polymerization initiated with azo *bis* isobutyronitrile. With the molybdenum derivative the effect is somewhat greater, but it is still much less than the marked inhibition produced by carbon monoxide in the case of the corresponding metal carbonyl systems<sup>3</sup>.

Use of polyvinyl trichloroacetate as the halide in place of  $CCl_4$  leads to systems showing rapid gelation. As already shown<sup>4</sup> this implies that radical formation takes place by abstraction of a halogen atom from the halide by the metal derivative, leaving an organic radical (for example,  $\dot{C}Cl_3$  from  $CCl_4$ ) capable of initiating polymerization.

A change in the valency state of the metal atom naturally accompanies radical formation. Paramagnetic

species are produced from hexaphenylisocyno molybdenum (0) and molybdenum hexacarbonyl which may be shown from the hyperfine structure of their electron spin resonance spectra to be molybdenum compounds. No electron spin resonance signals are obtainable from the corresponding tungsten derivatives. Work is in progress to elucidate the nature of the valency change in the metals.

We thank Joseph Crosfield and Sons, Ltd., for financial support for one of us (K. H.) and the Mond Division, Imperial Chemical Industries, Ltd., for a gift of phenyl isocyanide.

## BIOPHYSICS

### Intrinsic Viscosity Measurements of Bovine Serum Albumin at Different Temperatures

INTRINSIC viscosity of bovine serum albumin has been measured by a number of workers<sup>1-6</sup> and values ranging from 3.7 to 4.5 were obtained. All the measurements were made within certain ranges of pH (5-7), ionic strength (0.1-0.2) and temperature (20°-28° C). It has been reported that the intrinsic viscosity of bovine serum albumin does not change within the aforesaid ranges of pH and ionic strength<sup>3,4</sup>. Naturally the question arises whether the difference in the values of intrinsic viscosity obtained by different authors can be attributed to: (1) the difference in the temperature of the solutions; (2) the difference in the samples, that is, the difference in the heterogeneity factors of the samples (albumin is always found associated with a small fraction of material of higher molecular weight). No experiment has yet been reported which can help in the solution of this problem. The heterogeneity factor of the different samples used by different authors is also unknown.

In the experiment recorded here the intrinsic viscosity of a particular sample of bovine serum albumin has been measured under the same condition of pH and ionic strength at different temperatures.

The sample was crystalline bovine plasma albumin, fraction V, obtained from L. Light and Co., Colnbrook, England. The diffusion coefficient of the present sample of serum albumin was obtained<sup>7</sup> as  $D_{25}^{0,w} = 6.73 \times 10^{-7}$  cm<sup>2</sup>/sec. The ultracentrifugal pattern of the present sample revealed the presence of about 6 per cent material of higher molecular weight.

The viscosity was measured with the help of an Ostwald type of capillary viscometer in a constant-temperature water bath ( $\pm 0.01^\circ$  C). The upper bulb of the viscometer had a volume of 20 c.c. The flow time of 0.1 M sodium chloride at 25° C was of the order of 16 min. The protein solution was prepared by measuring the dry weight with the help of a semi-micro balance and dissolving in 0.1 M sodium chloride. The solution was then filtered through a sintered glass filter. The protein concentration in the filtrate was measured with the help of a Zeiss PMQ 11 spectrophotometer ( $E_{1\text{cm}}^{278} = 6.67$  at 278 mμ). The flow times of the filtered protein solution and the solvent were measured. The ratio of the averages of five such readings in each case was taken as the relative viscosity ( $\eta/\eta_0$ ) of the protein at that particular concentration. The reduced viscosity of

the protein solution<sup>1</sup> was obtained by subtracting 1.00 from  $\eta/\eta_0$  and dividing the result by the corresponding protein concentration,  $c$  (g/ml.). Freshly prepared protein solution was used for each experiment.

Fig. 1 shows the plot of  $(\eta/\eta_0 - 1)/c$  against  $c$  for five different temperatures (14°-28° C). Experimental points for all the temperatures were found to fit well in a single straight line (drawn by the least square method) passing through them. The intrinsic viscosity  $[\eta]$  of bovine serum albumin was obtained equal to  $4.18 \pm 0.05$  (average deviation of the points from the straight line).

Fig. 1. Plot of reduced viscosity,  $(\eta/\eta_0 - 1)/c$ , against concentration,  $c$ , of bovine serum albumin in 0.1 M sodium chloride at different temperatures. The extrapolated value and the slope of the least-squares line passing through all the points are  $4.18 \pm 0.05$  and 19 respectively.  $\Delta$ ,  $14^\circ \pm 0.01^\circ$  C;  $\circ$ ,  $16.50^\circ \pm 0.01^\circ$  C;  $\bullet$ ,  $20^\circ \pm 0.01^\circ$  C;  $\blacktriangle$ ,  $25^\circ \pm 0.01^\circ$  C;  $\oplus$ ,  $28^\circ \pm 0.01^\circ$  C

The experimental value of  $\eta$  thus lies within the range of values reported by others. The present set of data further indicates that the temperature (within the range examined) affects significantly neither the slope nor the extrapolated value,  $\eta$ , of the plot of  $(\eta/\eta_0 - 1)/c$  against  $c$ . Indirectly this work indicates that the varied results obtained by different authors are due to the differences in the heterogeneity factor of the samples used and hence indicates the necessity of mentioning the heterogeneity factor of the sample while reporting the value of  $\eta$ .

## BIOCHEMISTRY

### Detection and Documentation of Lipids after Thin-layer Chromatography

A DETAILED description of methods for the detection of lipids after thin-layer chromatography was recently given by Mangold<sup>1</sup>. Many workers prefer spraying with 2',7'-dichlorofluoresceine or rhodamine G solutions and viewing under ultra-violet light, while others expose the chromatoplate to iodine vapours. Subsequent elution of the lipids and methylation of fatty acids for gas-liquid chromatography is possible because the phosphors do not disturb these procedures. In semi-quantitative and preparative scale thin-layer chromatography we prefer localizing by means of fluorescence which many of the separated lipid spots exhibit under ultra-violet light<sup>2</sup>. In

Table 1. PERCENTAGE COMPOSITION OF A MIXTURE OF FATTY ACID METHYL ESTERS BEFORE AND AFTER ULTRA-VIOLET EXPOSURE

Fatty acid	Before ultra-violet exposure	After ultra-violet exposure
Palmitic acid	19.6	16.6
Stearic acid	3.7	3.9
Oleic acid	12.0	12.4
Linoleic acid	61.3	63.2
Linolenic acid	3.4	3.9

this way there is no contamination by phosphors and no danger of structural alterations. This method, too, is superior to 'leading chromatograms' which do not reveal irregularities of separation. In order to have permanent records the fluorescent lipid spots may be photo-copied in a manner similar to that of Milton<sup>3</sup>.

Samples of chloroform-methanol extracts (2:1, v/v) of tissue or plasma were spotted in 2 cm bands 1.5 cm above the lower edge of thin-layer plates coated with 0.25–0.5 mm silica gel G. The lipids were separated by ascend-

ing elution with the solvent mixture petroleum ether (b.p. 30°–60° C), diethyl ether and acetic acid (85:15:1, by volume) according to Mangold and Tuna<sup>4</sup>. After drying at room temperature a sheet of Agfa 'Copyrapid' negative *CpM* paper was placed on the silica-gel layer. In order to keep chromatoplate and paper in contact the paper was covered with a second glass plate. Next, this device was turned and the thin-layer was exposed through the glass to ultra-violet light for about 10 sec at a distance of 20 cm from the lamp. A quartz-lamp, model 'Heraeus', a big laboratory model with a predominating wave-length of 366 mμ, was used as the ultra-violet source. The negative paper was then drawn through the Agfa 'Copyrapid' developer and dried. The lipid spots for subsequent elution, etc., were localized by a second exposure to ultra-violet light and traced with a needle.

Fig. 1 shows the absorbing spots of four total lipid extracts from plasma and the solvent front as white areas against a dark background. There is no advantage in preparing positive copies because minor components are often lost. This is exemplified in Fig. 2 which represents the positive copy of Fig. 1; the weak spot representing free fatty acids of the first plasma sample is absent.

The short exposure of the thin-layer plates does not lead to alterations in fatty acid structure. Table 1 gives the composition of a mixture of fatty acid methyl esters before and after thin-layer chromatography and a 5-min exposure to ultra-violet light. There is no significant difference between fatty acid methyl ester composition with and without ultra-violet exposure.

### Nitrate Reduction with Molecular Hydrogen in a Reconstituted Enzymatic System

In recent work from this laboratory<sup>1</sup> it was found that flavin nucleotides, the well-known co-factors of cyclic photophosphorylation, could mediate the transfer of electrons from illuminated spinach grana to nitrate in the presence of spinach nitrate reductase. Spinach ferredoxin was not the effective electron carrier in the process. The electrons were supplied by either water or reduced indophenol dyes, and neither pyridine nucleotides nor adenosinetriphosphate were required for the reduction of nitrate. Since the dark reduction of nitrate by molecular hydrogen has been reported to occur at the cellular level in photosynthetic purple bacteria<sup>2,3</sup> and in the alga *Ankistrodesmus braunii*<sup>4</sup>, we investigated the mechanism of nitrate assimilation in a reconstituted enzyme system using hydrogen gas-hydrogenase as the electron donor instead of illuminated grana. In similar experiments carried out previously<sup>5</sup> on the mechanism of the dark and light reduction of nitrite, it was found that the co-factor required in both cases was ferredoxin.

Table 1 shows that the dark reduction of nitrate to nitrite by electrons supplied by hydrogen gas (in the presence of added *Clostridium pasteurianum* hydrogenase) was mediated by flavin mononucleotide and required the presence of spinach nitrate reductase. The participation of flavin nucleotides in another metabolic process, the reduction of diphosphopyridine nucleotide by hydrogen, has been found in several microbial preparations<sup>6-8</sup>. Under our conditions, *Clostridium* ferredoxin was not active as electron carrier in the transfer of electrons from molecular hydrogen to nitrate.

Fig. 1. Negative ultra-violet copy of thin-layer chromatoplate. CHE, cholesterol esters; ME, fatty acid methyl esters; TG, triglycerides; FFA, free fatty acids; FCH, free cholesterol; DG, diglycerides; MG + PL, monoglycerides and phospholipids

Fig. 2. Positive ultra-violet copy of thin-layer chromatoplate. Same plate as in Fig. 1

Fig. 1. Reduction of flavin mononucleotide with hydrogen gas in the absence and in the presence of ferredoxin (Fd). The reaction mixture included, in a final volume of 3 ml., sodium phosphate buffer pH 7.0, 200 μmoles; *Clostridium pasteurianum* hydrogenase<sup>10</sup>, 0.9 mg; cysteine, 10 micromoles. The reaction was started by tipping in flavin mononucleotide (4 μmoles) or flavin mononucleotide (4 μmoles) plus purified *Clostridium pasteurianum* ferredoxin<sup>12</sup> (0.3 mg) from the side-arm of the Warburg vessels. Other experimental conditions as in Table 1.

Fig. 2. Diagrammatic representation of the role of flavin mononucleotide (FMN) or flavin adenine dinucleotide (FAD) in the reduction of nitrate. The transfer of electrons from flavins to nitrate is a dark reaction catalysed by the chloroplast nitrate reductase. Flavins themselves can be reduced either in the light (by grana) or in the dark (by hydrogen gas or reduced triphosphopyridine nucleotide, TPNH).

Whiteley and Woolfolk<sup>9</sup> have reported that the reduction of flavins with hydrogen by *Micrococcus lactylicus* hydrogenase required the presence of ferredoxin isolated from the same micro-organism. We have therefore tested the effect of *Clostridium* ferredoxin addition on the hydrogen uptake catalysed by *Clostridium* hydrogenase using substrate amounts of flavin mononucleotide as the electron acceptor. As Fig. 1 shows, the reduction of this coenzyme was not mediated by ferredoxin.

The role of flavin nucleotides in the photochemical and dark reduction of nitrate catalysed by spinach nitrate

Table 1. REDUCTION OF NITRATE WITH HYDROGEN GAS IN A RECONSTITUTED ENZYME SYSTEM

System	Nitrite formed (μmoles)
Complete	1.24
Nitrate omitted	0.00
Flavin mononucleotide omitted	0.11
Nitrate reductase heated	0.00

The reaction mixture included, in a final volume of 3 ml., ferredoxin-free *Clostridium pasteurianum* hydrogenase<sup>10</sup>, 5.4 mg; spinach nitrate reductase<sup>11</sup>, 4.2 mg; and the following in μmoles: sodium phosphate buffer, pH 7.0, 200; flavin mononucleotide, 0.4; cysteine, 10; potassium nitrate, 20. The reaction was carried out in Warburg manometer flasks at 27° C for 75 min under hydrogen. Nitrite was assayed by the method of Novak and Wilson<sup>14</sup>.

reductase is schematically represented in Fig. 2 (see ref. 1).

## Cholinesterase Catalysis

CHARACTERISTIC of all known schemes of esterase catalysis<sup>1-5</sup> is the assumption that the reactive form of serine pre-exists in the enzyme molecule before the interaction of enzyme with substrate or inhibitor. This seems to be unlikely, for why this very reactive form is not involved in side-reactions is still very vague. Moreover, the possibility of the preliminary activation of serine aliphatic hydroxyl, by means of such a weak base as imidazole<sup>3-5</sup>, is not convincing.

The scheme outlined here (Fig. 1) suggests that acetylcholine (ACh) participates in activation of the catalytic centre of the cholinesterase (ChE). On approaching inactive ChE (I) the ACh is adsorbed on to the surface of the ChE, this adsorption being orientated by the anionic site of the enzyme. As a result of this process, at first a hydrogen-bond between ACh carbonyl oxygen and imino-nitrogen of a histidine imidazole ring is formed. The formation of this bond increases the basicity of the azolic nitrogen and a re-arrangement of the active centre of ChE occurs. Then the second hydrogen-bond between the activated azolic nitrogen and serine hydroxyl arises. This bond increases the nucleophilic nature of the hydroxyl oxygen and stimulates its interaction with the carbonyl carbon on ACh. This appears to be the essence of the transformation of the enzyme into its active form and of the formation of an enzyme-substrate Michaelis complex (IIa → IIb). The redistribution of the electron density in the 8-member ring results in the formation of the covalent bond between serine oxygen and carbonyl carbon and in the elimination of choline molecule. So the acetyl enzyme is formed (III). Proton transfer from imidazole to choline molecule may be carried out by means of the acidic group of the ester site (the existence of such a group is supposed by some authors<sup>5,6</sup>). The repulsion forces which act between the carbonyl oxygen and the azolic nitrogen seem to change the mutual orientation of the acetyl serine and the imidazole ring. The latter results in the formation of the hydrogen-bond between carbonyl oxygen and imino-nitrogen. The effects connected with this are similar to those inducing the Michaelis complex formation and lead to the appearance of new bonds between the acetyl enzyme and water molecule and to the formation of the intermediate acetyl-enzyme-hydrate complex (IVa → IVb). The redistribution of electron density in the 8-member cycle results in the

Fig. 1

elimination of the acetic acid molecule and in the transformation of the enzyme in its initial inactive form (I). Proton transfer from the imidazole ring to the serine oxygen is rendered possible by the acidic group of the esteratic site.

The phosphorylation of ChE by organophosphorus inhibitors appears to proceed according to the same scheme with the exception that the phosphorylated enzyme practically does not react with water.

The principal features of the suggested mechanism are:

(1) It assumes the participation of the substrate in the enzyme catalytic centre formation, the process being in good agreement with Koshland's 'induced fit' theory<sup>6</sup>. The conformation alterations which seem to involve also the hydrophobic sites of the active surface of ChE serve as a basis for explanation of the observed phenomena in the interaction of organophosphorus compounds with ChE<sup>7-9</sup>.

(2) The processes of acetylation and deacetylation are based on the same mechanism, which leads to formation of the intermediate enzyme-substrate Michaelis complex in the former process and of the acetylenzyme-hydrate complex in the latter.

(3) The scheme presents a new explanation of the inability of the substrates and inhibitors containing C=S and P=S groups, respectively, to interact with ChE; the sulphur cannot form hydrogen-bonds which are essential for the activation of the catalytic centre of the enzyme.

## Uranyl Ions and Intestinal Hexose Transfer

It is well established that at least part of the glucose transfer mechanism in the intestinal epithelium lies close to the luminal border of the cell. As Rothstein<sup>1</sup> has shown that uranyl ions exert a surface action in yeast cells in inhibiting hexose transfer, and Ponz<sup>2</sup> and Ponz and Lluch<sup>3</sup> have shown that they interfere with absorption of actively transported sugars, the effect of uranyl nitrate on hexose transfer in the rat small intestine was investigated.

Experiments were carried out on sacs of rat everted small intestine, and the transfers of glucose, galactose and fluid were examined in the presence of uranyl nitrate. Uranyl nitrate was found to have two effects on glucose transfer from the mucosal fluid. In concentrations from  $10^{-5}$  M to  $3 \times 10^{-4}$  M, glucose entry from the mucosal fluid was reduced from 55 mg/h to 40 mg/h, while glucose metabolism was unaffected. These concentrations also reduced the fluid transfer stimulated by glucose initially present in the mucosal fluid but not by glucose initially present in the serosal fluid. This supports the view that uranyl nitrate at these concentrations inhibits the entry of glucose into the epithelial cell from the mucosal fluid. In higher concentrations uranyl nitrate ( $3 \times 10^{-3}$  M) reduced glucose metabolism from 19 mg/h to 9 mg/h.

When galactose was initially present in the mucosal fluid, uranyl nitrate ( $3 \times 10^{-4}$  M) did not inhibit galactose transfer, but in a concentration of  $3 \times 10^{-3}$  M it reduced galactose transfer from 22 mg/h to 12 mg/h. This shows that uranyl nitrate can affect glucose entry from the mucosal fluid in a concentration which does not affect entry of galactose, the latter being inhibited only at concentrations which affect metabolism.

Experiments were also performed in which glucose and galactose were initially present together in the mucosal fluid. Fisher and Parsons<sup>4</sup> have shown that in equimolar concentrations glucose inhibits galactose transfer, and we found also inhibition of galactose transfer when both were present in a concentration of 28 mM. However, when glucose (5.6 mM) and galactose (28 mM) were present together galactose transfer was increased from 21 mg/h to 36 mg/h. Galactose transfer was also stimulated by glucose (111 mM) in the serosal fluid. Although uranyl nitrate ( $3 \times 10^{-4}$  M) did not affect galactose entry when present alone, it inhibited the stimulation of galactose transfer by glucose (5.6 mM) initially present in the mucosal fluid.

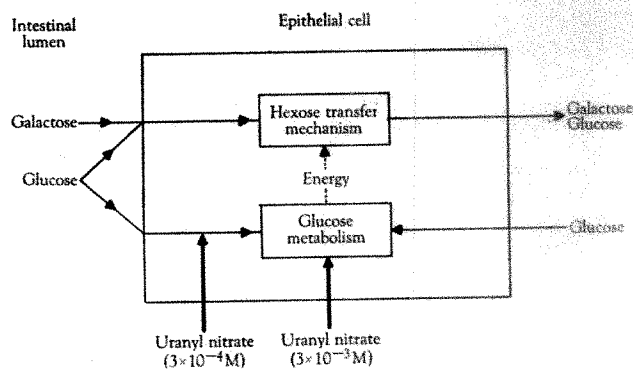

Fig. 1

Various explanations of these findings can be suggested. The most attractive is that illustrated in Fig. 1. This shows two different routes of entry of glucose into the cell from the intestinal lumen. One route is available to glucose only and not to galactose. It channels glucose into metabolism, and is blocked by uranyl ions. The second route is available to both glucose and galactose, and channels these into the mechanism for transfer against a concentration gradient. This route is not blocked by low concentrations of uranyl nitrate. Galactose transfer by this route can use energy from endogenous metabolism, but in addition can use energy from glucose metabolism. When glucose (5.6 mM) and galactose (28 mM) are present together with uranyl nitrate ( $3 \times 10^{-4}$  M) the two hexoses presumably compete for the one

pathway now available, and hence galactose transfer is inhibited.

Other explanations are also possible. There may be one mechanism for entry of hexoses into the cell, and the separation into two pathways—one uranyl sensitive leading into metabolism—may occur inside the cell. In this case it must be postulated that the uranyl sensitive pathway is not available to glucose initially present in the serosal fluid. Another possibility is that uranyl ions may penetrate only into a limited part of the cell and may affect metabolism of part of the cell into which glucose from the serosal side of the cell does not penetrate.

Of considerable interest is the stimulation of galactose transfer by small concentrations of glucose. Fisher and Parsons<sup>4</sup> showed that glucose and galactose compete for entry, and while the present results support this they also show that provided glucose is present in small concentrations in the mucosal fluid or in higher concentrations in the serosal fluid, it may be able to enter the cell without competing with galactose and by its metabolism stimulate galactose transfer. This would be in keeping with the results of Newey and Smyth<sup>5</sup>, who have shown that glucose metabolism can stimulate glycine transfer. It thus appears that glucose metabolism can supply energy for three different transfer systems, that is, galactose, glycine and fluid.

### Identification of Oestradiol and Oestrone in Avian Plasma

ALTHOUGH it has long been held that the plasma of the laying domestic fowl contains oestrogenic substances no direct identification has been reported. Although oestrone, oestradiol and oestriol have been identified in extracts of ovarian tissue from the laying hen<sup>1</sup> and also in urine<sup>2,3</sup>, attempts to detect oestrogens in blood have been unsuccessful.

As part of an investigation of factors involved in yolk production in the domestic fowl this problem has been investigated using a technique of double isotope derivative analysis<sup>4</sup> using carbon-14-labelled oestrogens and tritiated dimethyl sulphate as identifying agents.

Plasma from laying hens was treated with hydrochloric acid<sup>5</sup> to hydrolyse conjugated oestrogens, and after extraction with chloroform was separated into fractions presumptively containing oestradiol + oestrone and oestriol<sup>6</sup>. The fractions were methylated with dimethyl sulphate-T and, after removal of solvents and decomposition of excess dimethyl sulphate with alkali, were extracted into hexane. Authentic methylated <sup>14</sup>C-oestradiol and oestrone were then added and the methyl oestrogens were separated and purified, first by thin-layer chromatography using solvent systems A, B and C of Lisboa and Diczfaluzy<sup>6</sup>, followed by chromatography on columns of prepared alumina<sup>7</sup>. Samples of each fraction were counted in a liquid scintillation counter.

It was found that the samples of both methyl oestradiol and methyl oestrone contained tritium, the ratios of tritium/<sup>14</sup>C becoming constant after several fractionations (Table 1). As a further check on the chromatographic homogeneity, fractions eluted from the second alumina column (Table 1) were re-chromatographed on alumina and the three fractions comprising the beginning, the

middle and the end of each elution peak were separately collected. The tritium/<sup>14</sup>C ratios in each were found to be the same within the limits of experimental error (Table 2). At no time was tritium detectable in chromatographic areas corresponding to authentic methyl oestriol.

The results show that materials are present in hydrolysates of avian plasma which after methylation behave in a manner identical with methyl oestrone and methyl oestradiol in several solvent systems. Such behaviour is considered to be proof of identity and to show the existence of oestradiol and oestrone, or their conjugates, in avian plasma.

### An Extracellular $\alpha$ -L-Arabinofuranosidase secreted by *Sclerotinia fructigena*

AN earlier communication<sup>1</sup> reported the resolution of a maceration factor from endopolygalacturonase (PG) in culture filtrates of *Sclerotinia fructigena* Aderh. and Ruhl., by means of gel filtration on dextran Sephadex 'G 75' and chromatography on 'Ecteola'-cellulose. The biochemical basis of maceration of potato slices by these preparations was not elucidated, but McClendon<sup>2</sup> has demonstrated that, in chromatography on cellulose phosphate of an ultra-filtered and freeze-dried sample of our culture filtrate, maceration of potato disks occurred in two peaks, one associated with a major PG peak and the other with a minor PG peak, with indications that arabanase or galactanase may macerate. We have shown independently that arabinose is liberated from potato fibre by a purified 'maceration factor' preparation free of PG and, subsequent to McClendon's findings, from lupin seed pectate. Incubation of the purified preparation with potato fibre was also accompanied by a release of soluble uronide, as determined by the carbazole method<sup>3</sup> (Fig. 1); the uronide was shown to be of high molecular weight by its failure to pass through a 'Visking' dialysis membrane, suggesting that a partial breakdown of insoluble 'protopectin' had occurred.

'Protopectin' may owe its insolubility to the presence of linkages of uronides with galactans and arabans<sup>4</sup>, which are known to consist of chains of  $\alpha$ -L-arabino-

Fig. 1. Liberation of soluble uronide from potato fibre by 'maceration factor'. ●, Heated; ○, unheated

furanoside<sup>5</sup> and  $\beta$ -D-galactopyranoside<sup>6</sup> groups respectively. We have therefore examined the activity of culture filtrates of *S. fructigena* and of the purified 'maceration factor' in hydrolysing phenyl- $\alpha$ -L-arabinofuranoside<sup>7</sup> and *o*-nitrophenyl- $\beta$ -D-galactopyranoside<sup>8</sup> together with *o*-nitrophenyl- $\alpha$ -L-arabinopyranoside<sup>9</sup> and phenyl- $\beta$ -D-galactofuranoside<sup>10</sup> for comparison. The hydrolysis rates were determined at 25° and pH 4.7 by the usual estimation of the intensity of yellow colour due to *o*-nitrophenol liberation or, in the case of the unsubstituted phenyl glycosides, by estimation of liberated phenol<sup>11</sup>. The results given in Table 1 show that, while the culture filtrates hydrolysed all four substrates at varying rates, only the arabinofuranoside was attacked by the purified preparation.

Table 1. HYDROLYSIS RATES AT 25° AND pH 4.7 OF PHENYL- $\alpha$ -L-ARABINOFURANOSIDE (AF), *o*-NITROPHENYL- $\beta$ -D-GALACTOPYRANOSIDE (GP), *o*-NITROPHENYL- $\alpha$ -L-ARABINOPYRANOSIDE (AP) AND PHENYL- $\beta$ -D-GALACTOFURANOSIDE (GF)

Substrate	Initial concn. (mM)	Hydrolysis rate ( $\mu$ h/ml. enzyme) Culture filtrate	Purified 'maceration factor'
AF	1.11	7.02	1.52
GP	1.11	2.56	0.00
AP	1.23	0.59	0.00
GF	0.98	0.10	0.00

In support of the hypothesis that *Sclerotinia* maceration factor is identical with  $\alpha$ -L-arabinofuranosidase, it was found in preliminary experiments that the thermal inactivation pattern of the enzyme appeared to follow that of the maceration of potato disks assessed by Brown's method<sup>12</sup>.

The presence of the enzymes was also demonstrated in filtrates of 11-day-old cultures on pectate media of several other fungi known to secrete macerating enzymes—*Botrytis cinerea*<sup>13</sup>, *Penicillium expansum*<sup>14</sup>, *Rhizoctonia solani*<sup>15</sup>, and *Sclerotinia sclerotiorum*, and in an extract of carrot tissue rotted by the last-named fungus<sup>16</sup>.

These results nevertheless do not preclude the possibility that maceration is due to a substance distinct from  $\alpha$ -L-arabinofuranosidase, but of similar behaviour in the purification procedure adopted and which, if an enzyme, has a substrate not yet biochemically defined.

We thank Prof. B. Lindberg and Dr. Per Jerkeman for samples of phenyl- $\alpha$ -L-arabinofuranoside and phenyl-

$\beta$ -D-galactofuranoside, and Prof. J. H. McClendon for a sample of lupin seed pectate.

## PHYSIOLOGY

### Influence of External Stimuli on the Secretory Rate of the Avian Nasal Salt Gland

It was noticed during a series of experiments dealing with the functional capacity of the salt gland of sea-gulls that an increase in secretion rate was occasionally associated with 'alertness' caused by distant moving objects or from sudden noises.

In order to prove or disprove this impression, eight sea-gulls were subjected to either photic or auditory stimuli following a minimal salt load<sup>1</sup>, which induced the secretion of nasal fluid from the salt glands. The stimuli were applied shortly after the maximum secretory rate had been reached, at a time when the flow rate was subsiding.

Photic stimulation was produced by repeatedly shining a flashlight into the eye of a gull for periods varying from 2 to 10 min at a distance which did not induce 'escape' movements. In all instances light increased the secretory rate of nasal fluid produced by the salt gland

Fig. 1. Typical response of a salt-loaded gull to a light stimulus (L), the duration indicated by the bar. Notice the increased rate of nasal fluid secretion

Fig. 2. Typical response of a salt-loaded gull to an auditory stimulus (A), the duration indicated by the bar. Notice the increased rate of nasal fluid secretion

(Fig. 1) 0.5–3 times that noted immediately before applying the stimulus.

The sound stimulus was made with a quitter using individual notes, chords or a melody. Sound increased the secretory rate of nasal fluid (Fig. 2) in the same manner and degree as noticed with light stimulation.

These observations may be explained by assuming that photic or auditory stimuli increase the general excitability of the central neuropile and by facilitation augment the activity of the parasympathetic fibres innervating the gland<sup>2</sup>. These parasympathetic fibres are believed<sup>2</sup> to pass with the facial nerve, and presumably take origin near the motor nucleus of the facial nerve in the medulla oblongata. It is believed<sup>3</sup> that in the central nervous system there are osmoreceptors which react to increased osmolarity of the blood by exciting the parasympathetic fibres that stimulate salt gland secretion. If this is the case, then the finding that light or sound can enhance salt gland activity suggests that the final common parasympathetic pathway is influenced by neurons besides those from the osmoreceptors.

### Endogenous Shock-inducing Factor in Canine Haemorrhagic Shock

DURING recent work in this laboratory<sup>1,2</sup> it was shown that a transferable 'shock-inducing factor' appears in the plasma of endotoxin-shocked adrenalectomized dogs. This factor was heat-unstable (56° C, 30 min) and seemed to act as a histamine-liberator on the liver and induced a marked hepatosplanchnic blood pooling. Moreover, it was shown that a similar factor can be extracted from the liver slices of the shocked animals by cold physiological saline solution. Thus the extreme susceptibility of adrenalectomized dogs to endotoxin has been attributed to the liberation of the 'shock-inducing factor' from the

liver as the consequence of the disturbed hepatic metabolism after taking up endotoxins in the hepatic reticulo-endothelial cells. Pre-treatment with glucocorticoid could prevent both the hepatic metabolic disturbances, such as acute depletion of glycogen, and the release of the 'shock-inducing factor'.

Here it was intended to examine whether a similar 'shock-inducing factor' takes part in the progression of canine haemorrhagic shock in the absence of glucocorticoids or not. Experiments were made on unanesthetized adrenalectomized dogs well maintained with DCA. The animals were allowed to bleed from a femoral artery into an elevated heparinized reservoir until the blood pressure stabilized at 45 mm mercury. This rather high level of blood pressure was necessary for adrenalectomized dogs in order to prevent an early onset of respiratory failure. After about 3–4 h, when the 'up-take' of the blood (self-transfusion) was more than half the shed blood, the animals were bled and the plasma was tested by transfusing to 'Nembutal'-treated normal dogs. The compatibility of the recipients had been tested by a cross-match blood test beforehand.

As shown in Fig. 1, the transfusion of the plasma (10 c.c./kg) could induce a marked delayed depressor response in the recipient dog. The 'shock-inducing factor' shown here was quite similar to that observed in the endotoxin-shocked adrenalectomized dogs and was found to be heat-unstable; completely inactivated by heating to 56° C for 30 min, but not by heating to 53° C for 15 min which destroys the complement. It was precipitable by 34 per cent saturation with ammonium sulphate.

The depressor response was due to hepatosplanchnic blood pooling similar to that induced by histamine-liberators. The latency of the response was long, and the fall in blood pressure appeared usually a few minutes after the end of the plasma infusion. Moreover, the saline extract of the liver slices of the shocked animals was found to contain a similar factor, indicating its hepatic origin<sup>2</sup>.

The progression of the 'up-take' was accompanied by a progressive hypoglycaemia with marked lactacidaemia. Administration of hypertonic glucose solution could easily recover the hypoglycaemia, but not the progress of the 'up-take'. The marked increase in glucose tolerance characteristic of endotoxin shock in adrenalectomized dogs<sup>2</sup> was not observed. These clearly indicated that the

Fig. 1. Effect of transfusion of the plasma of shocked adrenalectomized dog to a 'Nembutal'-treated intact dog. The plasma lost its depressor activity when heated to 56° C for 30 min.

depletion of the liver glycogen and the accompanying hypoglycaemia here observed were not the result of the special derangement of carbohydrate metabolism in endotoxaemia. Moreover, the fact that the characteristic leucopenia in response to shock-dose of endotoxin was not observed indicated that endotoxins or macromolecular tissue substances did not participate in inducing the development of the 'shock-inducing factor'. In this respect the endotoxin hypothesis of Fine *et al.*<sup>3</sup> for the irreversible haemorrhagic shock does not seem acceptable.

The 'shock-inducing factor' was not detected either in plasma or in the liver extract when the animals succumbed to respiratory failure before marked 'up-take' supervened. When the adrenalectomized dogs were treated with glucocorticoids the tendency to hypoglycaemia did not proceed so much within the hypotensive period of 5 h and the 'shock-inducing factor' was not found in detectable amounts in the plasma. In the presence of glucocorticoids, therefore, the anoxic deterioration of the hepatic function leading to the glycogen depletion and to the liberation of the 'shock-inducing factor' seemed to be markedly ameliorated. The significance of glucocorticoids was also obvious in their central analeptic action<sup>4</sup> preventing the early onset of respiratory failure. The fact that glucocorticoids could not prevent the action of the 'shock-inducing factor' once liberated, as was clear in the transfusion experiments on intact dogs, might suggest their applicability to haemorrhagic shock is limited.

In passing, it may be noted that Wiggers<sup>5</sup>, observing the progress of irreversible haemorrhagic shock after restitution of blood volume by re-infusion of all the withdrawn blood (normovolemic shock), mentioned that hepatic resistance contrary to all other organs examined increases markedly and is chiefly responsible for the elevated portal pressure. This might perhaps indicate the participation of the 'shock-inducing factor' shown here, although the amounts liberated are too small to be detected by the passive transfer technique because of the presence of adrenal cortex. Why clear experimental evidence has not been hitherto available that endogenous toxins are concerned as a cause or contributory factor in shock might be due to the fact that the experiments have been exclusively made on intact animals. The significance of the 'shock-inducing factor' in the development of the irreversibility of shock in intact animals will be further investigated.

### Oral Treatment of Pernicious Anaemia

HEATHCOTE and Mooney<sup>1</sup> reported in this journal their clinical results from treating two cases of pernicious anaemia with a vitamin B<sub>12</sub> glutamic acid mixture, and we published<sup>2</sup> our own results of Schilling tests with and without L-glutamic acid in patients with pernicious anaemia. Our results showed that glutamic acid does not in general increase the absorption of vitamin B<sub>12</sub> measured by the Schilling test. In their reply<sup>3</sup> Mooney and Heathcote disregarded our results, doubting whether the Schilling test has in fact any physiological merit at all. Although we cannot concur in their opinion of the Schilling test, we decided to investigate the problem from another aspect as well.

The essential weakness in the study by Heathcote and Mooney, in our opinion, was the too short control period

Fig. 1

with oral vitamin B<sub>12</sub> alone. It was just this point which originally made us doubt the significance of glutamic acid. However, as Heathcote and Mooney emphasize the importance of the type of test they used, we treated one pernicious anaemia patient in the same manner, that is, with 60 µg of vitamin B<sub>12</sub> daily orally, except that the glutamic acid additive was omitted. The result is seen in Fig. 1. The development of the blood picture of our case is traced as a dotted line on a copy of Heathcote and Mooney's Fig. 1 (ref. 1). We followed our case for 50 days only, but it is quite apparent that the increase in haemoglobin and packed cell volume is as good as in their case. This we in fact expected, but in addition the reticulocyte curve displayed several successive peaks. We thus obtained a completely similar haematological progress by prolonging the mere vitamin B<sub>12</sub> 'control period' sufficiently.

As, according to Ross *et al.*<sup>4</sup>, about 1 per cent of an oral vitamin B<sub>12</sub> dose is absorbed even without the intrinsic factor, about 0.6 µg daily would be absorbed from 60 µg. This is practically the same as the 1 µg which, given parenterally, suffices in the opinion of Bethel *et al.*<sup>5</sup> to cause remission in pernicious anaemia. It is understandable, then, that the 60 µg dose sufficed, completely independent of the concomitant administration of glutamic acid.

In our opinion, therefore, Heathcote and Mooney's work does not prove that oral administration of vitamin B<sub>12</sub> is more efficacious in cases of pernicious anaemia when administered together with glutamic acid. That the same therapeutic result may in fact be achieved with vitamin B<sub>12</sub> alone, as we have now shown, could have been presupposed from the results of our earlier Schilling tests<sup>2</sup>.

ILMARI PALVA  
OLLI HEINIVAARA

University of Helsinki, Finland.

<sup>1</sup> Heathcote, J. G., and Mooney, F. S., *Nature*, **193**, 380 (1962).

<sup>2</sup> Heinivaara, O., and Palva, I., *Nature*, **199**, 289 (1963).

<sup>3</sup> Mooney, F. S., and Heathcote, J. G., *Nature*, **199**, 290 (1963).

<sup>4</sup> Ross, G. I. M., Mollin, D. L., Cox, E. V., and Ungley, C. C., *Blood*, **9**, 472 (1954).

<sup>5</sup> Bethel, F. H., Meyers, M. C., and Neligh, R. B., *J. Lab. Clin. Med.*, **33**, 477 (1948).

It will not surprise many workers in the B<sub>12</sub> field to read that Dr. Heinivaara and Dr. Palva have obtained a remission over a period of 50 days in one case of perni-

cious anaemia, which was receiving a daily dosage of 60  $\mu$ g of crystalline B<sub>12</sub> (see above). Indeed, in our original work<sup>1</sup> we chose this dosage because we knew that, being in the sub-optimal range, it should be sufficient to prevent deterioration during the period of test, and thus be ethically justifiable. To draw firm deductions about the significance of glutamic acid additives, however, from a comparison between the blood responses in two selected cases is too ingenuous. The important finding, of course, during this initial period of treatment on sub-optimal dosage is not the haematological response as assessed by haemoglobin (Hb) or packed cell volume (P.C.V.) readings over 50 days (which vary greatly from patient to patient), but the reticulocyte response, obtained from the same patient, on one form of therapy compared with that on another. This test—the double reticulocyte response test—is not our test as Heinivaara and Palva infer. It was originally described in 1935 by Minot and Castle<sup>2</sup>, and is still regarded as the most reliable short-term method for the comparison of the therapeutic effect of two haematinics of unknown potency<sup>3</sup>.

Our control periods were actually within the limits laid down by the authors of the test, but in view of these criticisms we would like to quote another case from our series—which has hitherto remained unpublished—in which the additive was a tripeptide derivative of glutamic acid (glutathione). In this particular case the control period of treatment with vitamin B<sub>12</sub> alone was more than a year. Certainly it will serve just as well as glutamic acid itself in resolving the basic disagreement as to whether an 'intrinsic factor' exists or not. The B<sub>12</sub>/glutathione was prepared by a simple admixture by weight in a 1:1 ratio. Thus the glutathione was considerably less than that used when a mixture of B<sub>12</sub> and glutamic acid was used (1:5).

Fig. 2

The patient (case No. 41) was a married woman aged 38 suffering from previously untreated pernicious anaemia which was diagnosed by the methods outlined in our previous report<sup>1</sup>. Her haemoglobin (Hb) at the commencement of treatment was 54 per cent, and the packed cell volume (P.C.V.) was 20.5 per cent (Fig. 2). She received 20  $\mu$ g of B<sub>12</sub> plus 20  $\mu$ g of glutathione orally per day, responded well, and was maintained on this dosage until the 589th day, when the glutathione additive was omitted, and she then received 20  $\mu$ g of crystalline B<sub>12</sub> only each day. At that time the Hb was 89 per cent and the P.C.V. 43 per cent. She remained well—presumably due to accumulation of B<sub>12</sub> previously acquired—until the 894th day when a fall was noticed which continued without arrest, until by the 957th day the Hb was 70 per cent and the P.C.V. was 28 per cent. The glutathione additive (20  $\mu$ g) was then restored to the daily dose of crystalline B<sub>12</sub>. The control period on B<sub>12</sub> alone lasted, therefore, 368 days.

The result of the addition of glutathione in treatment is clearly shown by the satisfactory recovery in the blood picture. Indeed, it was possible on the 993rd day to reduce the daily dosage to 10  $\mu$ g each of B<sub>12</sub> and glutathione, and the patient has remained on this ever since. Currently (1,268th day) the Hb is 97 per cent and the P.C.V. is 40 per cent. This clearly demonstrates, once more, that an enhanced therapeutic effect of B<sub>12</sub> may be achieved by the addition of a relatively simple substance—in this case a tripeptide of glutamic acid.

It is relevant to mention the present state of the two previously reported cases<sup>1-4</sup> which have been maintained on the mixture of glutamic acid and B<sub>12</sub>, should Drs. Heinivaara and Palva wish to follow up our work a little further. Case No. 49 has now been on treatment for 1,361 days and during that time he has received an average daily dose of 25  $\mu$ g of B<sub>12</sub> admixed with glutamic acid in a 1:5 ratio. His Hb is 90 per cent and his P.C.V. is 40 per cent. He has remained on a daily dose of 20  $\mu$ g of B<sub>12</sub> (given with glutamic acid) since the 382nd day of treatment. Case No. 52 has been on treatment for 1,331 days. His Hb is 100 per cent and his P.C.V. is 43 per cent. The average daily dose of B<sub>12</sub> (given with glutamic acid) is 22  $\mu$ g, and he has been on a daily dose of 20  $\mu$ g since the 180th day of treatment.

### Thalamo-cortical Relations in the Sensory Nuclei of the Cat

THE concept of the control of the somatic afferent pathways by the higher levels of the nervous system, first put forward by Hagbarth and Kerr<sup>1</sup>, has received considerable support from subsequent experiments involving the study of the activity of single neurones in the sensory tracts and nuclei. In particular, the dorsal column nuclei have been studied in detail with anatomical and physiological techniques<sup>2</sup>, and Eccles and Lundberg and their co-workers have demonstrated recently that stimulation of areas S I and S II of the cerebral cortex causes presynaptic inhibition on the afferent fibres relaying with the cells of the dorsal horn and cuneate nucleus<sup>3-7</sup>. Recent experiments have shown that the cerebral cortex can also influence the activity of the higher levels of the sensory pathways, namely the activity of some of the thalamic relay nuclei.

These experiments were performed in cats under chloralose, and gallamine triethiodide. Records were taken by means of concentric electrodes insulated except at the tip, introduced stereotactically into the thalamus in the ventro-basal complex (VB), in the posterior group of nuclei (POn) and other thalamic nuclei. The VB and POn have quite different physiological properties<sup>8-10</sup>.

(i) While the neurones of the VB have a precise somatotopic organization and respond only to appropriate contralateral stimulation, the POn receive afferent impulses

from large bilateral regions of the body, from surface as well as deep sensory nerves, from somatic and visceral (splanchnic) afferents and from the auditory pathways. Activity in any one of the neuronal groups of the PON can be evoked—as a rule—by stimulation of any of the four limbs (Fig. 1).

(ii) The latency of the PON response to contralateral stimulation is only slightly longer than that of the VB. However, the activity evoked by ipsilateral stimulation has a latency which is more variable generally: it is 2–3 msec longer than that of contralateral stimulation, but it may be much longer than can be accounted for by direct transmission of impulses to the PON.

(iii) While the activity evoked in the VB in response to a single shock to a peripheral nerve is brief (for example, 10 msec), the evoked activity in the PON in response to a similar stimulus is a prolonged discharge lasting 30–40 msec.

(iv) In general the activity in the PON evoked by a single stimulus to a peripheral nerve consists of a series of potential waves which are small and fast at the beginning, gradually increasing in voltage and then decreasing smoothly. In other cases, however, the activity consists of two distinct phases: an early phase of small and fast waves followed by a late phase of larger 500–700/sec oscillations. There is no time interval between the two phases, the early one fading into the late phase without any break. But the two phases can be easily distinguished, not only by the type of activity but also by their origin. It has been possible to abolish the

Fig. 1. Potentials recorded in the PON of the thalamus after single shock stimulation of the cutaneous nerves of the limbs. At the signal stimulation of skin nerves of: A, contralateral anterior paw; B, ipsilateral anterior paw; C, contralateral posterior paw; D, ipsilateral posterior paw. Time calibration, 20 msec. Voltage calibration, 100  $\mu$ V

Fig. 2. Potentials recorded in PON of the thalamus on stimulation of cutaneous nerves of anterior contralateral paw; A, B, control; C, D, 90 sec after freezing the sensory-motor area of the cerebral cortex, E, F, after re-warming the cerebral cortex. Time calibration in E, 20 msec

late phase of PON activity by freezing or damaging the sensory cortex, leaving the first phase unaffected (Fig. 2). This shows that the late phase of PON activity is of cortical origin, and probably due to impulses reflexly discharged when afferent impulses reach the cortex. If this is so, it would be expected that stimulation of the sensory areas of the cerebral cortex would cause a similar type of activity in the PON. This has been verified experimentally, and it has been found that a burst of waves very similar to those of the late phase is produced in the PON by stimulation of the cortex. It has been possible to exclude the possibility that this activity is due to antidromic stimulation of the afferent cortical fibres, because a similar type of activity appears in the PON contralateral to the stimulated cortex.

It can be concluded, therefore, that the arrival of afferent impulses to the cortex causes the discharge of impulses which affect the PON bilaterally and that the late phase is due to neurones different from those acting in the first phase or to a different degree of synchronization in their discharge.

In addition to these excitatory effects on some cellular groups of the PON, the sensory areas of the cortex exert an inhibitory effect on other functions of these nuclei. Following 2–5 shocks to the SI or SII areas of the cortex, there occurs a deep depression and even a complete disappearance of the evoked potentials in the PON (Fig. 3). This is not a general effect on all the relay nuclei of the thalamus, because it does not occur in the VB, although there is evidence that it involves not only the PON but also other neighbouring nuclei. We are dealing here with a powerful inhibitory effect, as two or three shocks may be sufficient to prevent the appearance of any sign of evoked activity for 200 msec. It is rather difficult

Fig. 3. Cortical inhibition of evoked potentials recorded in the POn of the thalamus. A, potential produced by stimulation of cutaneous nerves of the anterior contralateral paw by single shock at the signal; B, C, D, stimulation of cutaneous nerves of anterior contralateral paw as in A, but cutaneous stimulus is preceded by three shocks applied to the anterior suprasylvian gyrus of the contralateral cerebral cortex. Note the almost total inhibition of the evoked potentials, and the fact that this inhibition occurs both when the cortical stimulation causes activation of the POn (B, C) and when this activation is absent (D). Time calibration in A.

to establish the early course of the inhibitory process, as inevitably cortical stimulation will cause excitation of groups of neurones in the POn, thus masking the inhibition of the evoked potentials. When the cortical shocks and the peripheral stimuli are delivered at the appropriate time interval there is no evidence of peripherally-evoked activity superimposed on the cortically-induced impulses, or of summation of these two types of activity at all the intervals tested. Lack of summation might indicate a complete occlusion, but this is unlikely, as units which are normally excited from the periphery may be completely inhibited by preceding cortical stimulation without being themselves activated by it (Fig. 3D). It would seem, therefore, that cortical stimulation causes a profound inhibition of the responses of the POn.

• The physiological role of these mechanisms is still a matter for speculation. It may be thought that this cortically-induced inhibition of the POn relay nuclei might be part of the effects produced by the cerebral cortex when it

discharges following the arrival of sensory impulses to the cortex. The inhibition of transmission at the POn, but not at the VB, would allow access to the cortex to afferent impulses mediated by the medial lemniscus such as kinesthetic impulses, which are of relevance to motor action, while it would cut out other sensory messages irrelevant to the action performed, and which may be considered at this juncture as interfering sensory noise. Similarly the presynaptic inhibition exerted by the cortex, possibly through the pyramidal tract, on the dorsal horn and cuneate nucleus neurones, affects all afferent fibres but those of I A group. There is no presynaptic inhibition mediated by the cortex on the neurones of the dorsal spino-cerebellar tract activated exclusively by group I afferents<sup>7</sup>. It appears that, as a general rule, the inhibitory action of the cortex affects cutaneous and muscular afferents of high threshold, while the transmission to the cerebral and cerebellar cortex of impulses from kinesthetic and large muscular afferents having an important function in the origin and regulation of motor activity is not influenced by the cerebral cortex inhibitory mechanisms. These mechanisms may be one of the ways in which the cortex can initiate and direct the motor activity into the appropriate channels.

### A Modified Technique for collecting Mouse Thoracic Duct Lymph

TECHNIQUES for collecting lymph from unanaesthetized mice have been described by Shrewsbury<sup>1</sup> and Gesner and Gowans<sup>2</sup>, who cannulated the duct immediately below the diaphragm in a manner similar to that described by Bollman, Cain and Grindlay<sup>3</sup> for the rat.

In the mouse the abdominal part of the duct is closely adherent to the left postero-lateral aspect of the abdominal aorta, and attempts to encircle the duct with a ligature and tie the cannula in place, as described by Shrewsbury, frequently result in damage to one or both of these structures. Gesner and Gowans modified Shrewsbury's method of fixing and sealing the cannula in the duct by swinging a flap of quadratus lumborum muscle antero-medially and fixing it with a ligature to the emerging part of the cannula. In both methods there is a risk of dislodging the cannula from the duct during the insertion of the ligature; moreover, a second ligature needs to be inserted to provide further fixation of the duct to the posterior abdominal wall, and accurate insertion and tying of ligatures within the small operation field are difficult and time-consuming.

We have developed a simple and rapid method of fixing the cannula using a plastic adhesive, 'Eastman 910'. This substance is a monomer, methyl 2-cyanoacrylate, to which has been added a thickening agent, an inhibitor to stabilize it, and a plasticizing agent to prevent it from becoming brittle on ageing. The material has the appear-

ance and viscosity of water, and readily undergoes a rapid, highly exothermic, anionic polymerization to convert to a solid state forming strong bonds between a variety of materials.

Adhesion results from molecular attraction and mechanical grip action on irregular and porous surfaces<sup>4</sup>, and no heat, excessive pressure, evaporation of a solvent or addition of a catalyst is necessary. A minute amount of moisture on the surfaces to be united is desirable, however, since the polymerization is catalysed by water.

The adhesive has been shown to be inert, non-sensitizing to skin and relatively non-toxic, and evokes only a mild foreign-body reaction comparable in duration and severity to that caused by catgut<sup>5</sup>. It is said to be self-sterilizing<sup>6</sup>, but may if desired be sterilized by X-irradiation.

Reports have been published of the successful use of 'Eastman 910' as an adhesive in a variety of procedures including closure of skin incisions<sup>7</sup>, anastomosis of bowel<sup>8</sup>, and repair of blood vessels<sup>9-12</sup>.

Cannulae are made by threading a fine wire into a piece of 0.5 mm bore nylon tubing (Portland Plastics, Ltd.), bending to form a 'U' and immersing in an oil bath at approximately 130° C for about 30 sec. They are then hardened off at room temperature in methylene chloride, the wire is withdrawn, and one end is bevelled with scissors.

Six hours before operation all food is withdrawn, and 4 h later the mice are given 0.2 ml. olive oil by gastric tube.

The abdomen is opened under 'Avertin' anaesthesia by an incision following the lateral border of the left quadratus lumborum muscle, and the left kidney is mobilized and retracted medially. The duct is exposed by carefully dissecting the fatty retro-peritoneal tissue from the lateral aspect of the aorta and displacing it medially on to the anterior surface of that vessel.

The cannula is passed through the flank of the animal by means of a trocar, and the bevelled end is inserted directly into the duct with a quick stab. The fatty retroperitoneal tissue which was dissected off the lateral surface of the aorta is re-positioned across the junction of cannula and duct, and a small drop (about 0.005 ml.) of 'Eastman 910' is applied with a glass pipette. Within 30 sec polymerization occurs and the cannula cannot readily be dislodged from the duct. A further drop of adhesive is applied to fix the cannula to the posterior abdominal wall, after which the kidney is replaced, the muscle layers are closed with interrupted black silk sutures, and the skin is closed by a further application of 'Eastman 910'.

After operation the mice are warmed on an electric blanket for a few minutes and given 4 I.U. heparin in 1 ml. saline by subcutaneous injection. They are then placed on rotating drums of the type used by Gesner and Gowans<sup>3</sup>, and secured by a loop of adhesive tape around the thorax, and a further strip of tape which fixes their tails to the posterior part of the apparatus. Food and dextrose saline are available *ad lib*. Any small clots which form in the cannula are removed with a piece of fine stainless steel wire—a more effective instrument, in our experience, than the human hair used by Gesner.

Using this technique with adult pure-line (CBA) mice of either sex we have obtained a mean volume of 19 ml. of lymph in 24 h from those animals which drink well post-operatively. The mean total cell count in the first 24 h specimens was 84 million, which is somewhat less than the value reported by Gesner and Gowans. It is felt this difference may be due to the small size of the inbred mice which we have used, or to the fact that these mice, for the purposes of our experiments, had been pre-immunized with A-strain mammary carcinoma cells.

This work was supported by the British Empire Cancer Campaign for Research. One of us (J. L. B.) is a Medical Research Council Junior Fellow. We thank Ethicon, Inc.,

for supplying the 'Eastman 910' and Portland Plastics, Ltd., for manufacturing the cannulae.

## PHARMACOLOGY

### Effect of Prostaglandin (PGE<sub>1</sub>) on the Permeability Response of Toad Bladder to Vasopressin, Theophylline and Adenosine 3',5'-monophosphate

THE prostaglandins (PGE), a group of naturally occurring fatty acids, have been isolated from a number of sources including sheep vesicular glands and human vesicular plasma<sup>1,2</sup>. The chemical nature and separation of this series of related analogues have been reported in detail<sup>3-4</sup>. They have profound effects on blood pressure and on smooth muscle contractility, and are also known to interfere with the action of a variety of hormones on adipose tissue<sup>5-7</sup>. Because of the possibility that the prostaglandins may have other physiological effects of a more general nature, and perhaps serve as regulators of hormone action in certain tissues, the effect of one of them, PGE<sub>1</sub>, on the response of the toad bladder to vasopressin, theophylline and adenosine 3',5'-monophosphate (cyclic-AMP) was examined. All three of the latter compounds, when added to the serosal surface of the isolated bladder of *Bufo marinus*, increase the osmotic flow of water across this membrane. It has been suggested that vasopressin exerts its permeability effects here and in the kidney by increasing the concentration of adenosine 3',5'-monophosphate within the tissue<sup>8</sup>. The cyclic-AMP is presumed to be the intracellular mediator of the vasopressin effect. Theophylline mimics vasopressin in toad bladder, since it inhibits the degradation of cyclic-AMP to inactive 5'-adenosine monophosphate<sup>9</sup>.

The increase in permeability to water induced by these agents, as manifested by an augmentation in net water movement along an osmotic gradient, can be estimated by a volumetric technique described by Edelman *et al.*<sup>10</sup>. In the present studies, a 7.5 sq. cm portion of toad bladder was clamped between two glass chambers. The chamber apposed to the blood or serosal surface of the bladder contained a modified Ringer's solution (pH 7.8, 220 mOsm); that apposed to the outer or mucosal surface contained hypotonic Ringer's solution (55 mOsm). Adequate mixing was assured by bubbling air through the serosal chamber. The rate of flow of water along the osmotic gradient from the mucosal solution to the serosal solution was measured by means of a graduated pipette.

Since *Bufo marinus* has a bi-lobed bladder, it was possible to use bladder halves from the same toad in all studies. One hemi-bladder served as the control, the contralateral one as the experimental side. Following

Table 1. EFFECT OF PGE<sub>1</sub> ON TOAD BLADDER

PGE <sub>1</sub>	Vasopressin 1 mU./ml.			Theophylline 10 <sup>-2</sup> M			Cyclic-AMP 10 <sup>-3</sup> M		
	n	$\Delta_{III}^*$ $\mu\text{L}/\text{min} \pm \text{S.E.}$	P†	n	$\Delta_{III}^*$ $\mu\text{L}/\text{min} \pm \text{S.E.}$	P	n	$\Delta_{III}^*$ $\mu\text{L}/\text{min} \pm \text{S.E.}$	P

1.7 × 10 <sup>-11</sup> M	—	—	—	5	+0.8 ± 0.8	—	—	—	—

\*  $\Delta_{III}$  is the mean of the differences between  $\Delta_I$  and  $\Delta_{II}$  as described in the text and is an index of the effect of PGE<sub>1</sub> on the permeability response to the three agents tested.

† P is the significance of  $\Delta_{III}$ .

n, number of paired experiments.

In the control periods the mean response to vasopressin was 6.1  $\mu\text{L}/\text{min}$ , to theophylline 6.1  $\mu\text{L}/\text{min}$ , and to cyclic-AMP 4.1  $\mu\text{L}/\text{min}$ .

a preliminary period in plain Ringer's solution in which there was negligible osmotic flow of water across the bladder, the test agent, vasopressin (1 mU./ml.  $\approx 2 \times 10^{-9}$  M), theophylline (10<sup>-2</sup> M) or cyclic-AMP (10<sup>-3</sup> M) was added to the serosal bathing medium of the two hemi-bladder preparations. The concentrations of test agents were selected to yield a submaximal increase in water movement. The difference in response of the two sides with respect to water movement ( $\Delta_I$ ) was measured over a 20-min period. The bladders were then reintroduced into fresh Ringer's solution until the initial impermeability was re-established. Following this the same concentration of test agent as originally used was added to both bladder halves, and PGE<sub>1</sub> in concentrations varying from 1.7 × 10<sup>-6</sup> M to 1.7 × 10<sup>-11</sup> M was added to the serosal solution bathing the experimental side only. The difference in response of the two sides was again observed ( $\Delta_{II}$ ) for 20 min. The means of the differences between  $\Delta_{II}$  and  $\Delta_I$  are noted in Table 1 and are an index of the effect of PGE<sub>1</sub>.

It is apparent that PGE<sub>1</sub> significantly diminishes the permeability response of the toad bladder to vasopressin and to theophylline, but not to cyclic-AMP. The inhibitory effect is reversible and is not induced by the addition of PGE<sub>1</sub> to the mucosal bathing medium. Although 1.7 × 10<sup>-7</sup> M–1.7 × 10<sup>-10</sup> M PGE<sub>1</sub> effectively inhibited the theophylline response in the present studies, whereas 1.7 × 10<sup>-6</sup>–1.7 × 10<sup>-9</sup> was effective for vasopressin, a somewhat different result was obtained in earlier experiments. In these, whole bladder sacs were used according to the method of Bentley<sup>11</sup> in which net water movement is estimated by measuring the weight loss of the toad bladder sac over an appropriate period of time. 10<sup>-8</sup> M PGE<sub>1</sub> interfered with the effect of vasopressin in the earlier studies as in the present experiments, but did not inhibit the response to theophylline. In the latter instance, an apparent enhancement of the theophylline effect was observed. The significance of this difference in results with two different techniques and concentrations of PGE<sub>1</sub> is obscure. However, in the earlier experiments as well as those reported herein the effect of cyclic-AMP on water movement was uninfluenced by PGE. It should be noted that PGE<sub>1</sub> alone has no effect on permeability and that ricinoleic acid, a fatty acid which in some studies served as a control for PGE, did not influence the response to vasopressin, theophylline, and cyclic-AMP, attesting to the relative specificity of the inhibition by prostaglandin.

No other naturally occurring compound in these concentrations is known to alter the response of this tissue to vasopressin. Cysteine, in considerably higher concentrations, 10<sup>-3</sup> M, limits the response to vasopressin and theophylline but not to cyclic-AMP<sup>12</sup>. It is conceivable that PGE may, in fact serve as a regulator of hormone action with respect to antidiuretic hormone. Vasopressin increases cyclic-AMP concentration in toad bladder<sup>13</sup> and also activates the enzyme phosphorylase in this tissue and in kidney<sup>14</sup>. The effect of PGE on the

concentration of cyclic-AMP and on phosphorylase activation in this tissue has not as yet been examined, although it has been reported that phosphorylase activation induced by epinephrine in adipose tissue is inhibited by pre-incubation of the tissue with prostaglandin<sup>7</sup>.

### Effect of Anaesthetics on the Duration of Embolization of Platelet Thrombi formed in Injured Blood Vessels

WHEN an artery of the cerebral cortex of an anaesthetized rabbit is pinched with a pair of fine forceps so that it bleeds briefly, some platelets rapidly form a haemostatic plug outside the vessel and others adhere to its endothelial lining at the site of injury to form platelet clumps or 'white bodies' which embolize intermittently in the blood stream. The formation and embolization of white bodies may go on for several hours<sup>1-3</sup>.

These observations were made on rabbits anaesthetized with urethane. In continuing an investigation designed to discover substances capable of inhibiting the formation of white bodies<sup>4,5</sup>, we wanted to use animals smaller than rabbits in order to save material. We found that, in rats, the response of cortical vessels to mechanical injury was similar to that in rabbits except that, under apparently similar conditions, the embolization of white bodies appeared to stop sooner. In rats, both arteries and veins

were injured and embolization in both lasted for about the same periods of time. In the course of the experiments an interesting difference in the duration of embolization was observed depending on whether the rats were anaesthetized with sodium pentobarbital or ether instead of with urethane. The experiments which showed this difference were as follows:

Male and female albino rats of the Wistar strain, weighing 190–250 g, were anaesthetized and the skull and dura carefully removed from one cortex to expose an area measuring about  $15 \times 7$  mm. This area was kept moist by a gentle flow of warmed physiological saline and the temperature of the cortical surface was maintained at about  $30^\circ\text{C}$ . The exposed vessels were observed under a Zeiss model II dissecting stereomicroscope at a magnification of 42 times. A vein, about  $100\mu$  in diameter, was injured by pinching it with fine ophthalmic forceps so that it bled for 10–40 sec (under ether anaesthesia the bleeding usually went on for 90 sec or even longer). White bodies began to form after 2–5 min and the time from the embolization of the first white body to that of the last was recorded. Several veins in each rat were injured and timed in this manner and the longest period of embolization was used for statistical comparisons.

Table 1 shows that injured cortical vessels produced embolizing white bodies for significantly longer periods of time under urethane anaesthesia than under anaesthesia with either sodium pentobarbital or ether. It seems, therefore, that urethane in anaesthetic concentrations greatly prolongs the production of platelet thrombi in injured vessels.

Anaesthetic	No. of rats	Range	Duration of embolization (min) Mean	S.E.M.	P
Sodium pentobarbital	11	4–61	$18.9 \pm$	$5.79$	} 0.001
Urethane	10	47–240+	$106.7 \pm$	$19.64$	
Ether	8	4–43.5	$20.4 \pm$	$4.91$	} 0.001

This observation is presumably related to the irritant and cytotoxic properties of urethane. Urethane has been used as a sclerosing agent in the treatment of varicose veins<sup>4–10</sup> and as a cytotoxic agent in the treatment of leukaemia and other malignancies<sup>11–18</sup>. Urethane increases capillary permeability<sup>17,18</sup>, and it causes severe damage to portal veins and sinusoidal capillaries in rats<sup>19</sup>. These experiments suggest that urethane, in anaesthetic concentrations, somehow irritates vascular endothelium sufficiently to prolong the effects of mechanical trauma as indicated by the intravascular adhesion and aggregation of platelets.

## Antitumour Activity of *N*-( $\beta,\beta'$ -dichlorodiethylaminomethyl)-tetracycline, 'Tetracycline-mustard'

LOCALIZATION of tetracycline in tumour tissue has been reported with both human and animal neoplasms<sup>1</sup>. Though the tetracycline class antibiotics have no antitumour effect by themselves, the possibility of using them as carriers of more potent agents seemed worthy of investigation. As a model system a nitrogen mustard (HN2) derivative was considered most practical because of simplicity of structure, availability of starting materials and general knowledge concerning the antitumour activity of mustard type alkylating agents.

Preparation of *N*-( $\beta,\beta'$ -dichlorodiethylaminomethyl)-tetracycline was carried out according to the carboxamido-Einhorn derivative method of Gottstein, Minor and Cheney<sup>2</sup>. Fifty g of tetracycline base, 20.6 g of  $\beta,\beta'$ -dichlorodiethylamine hydrochloride (*nor* HN2), and 7 g of formaldehyde (14 ml. of 55 per cent methylformcel) were dissolved in 250 ml. of methanol. This solution was held at  $22^\circ\text{C}$  for 1.5 h and then added with rapid stirring to 3 l. of ethyl ether. The resulting precipitate was removed by filtration, washed with 300 ml. of ethyl ether and dried at  $50^\circ\text{C}$  *in vacuo* for 24 h. Fifty-five g of tetracycline-mustard Einhorn derivative (TCM) were obtained. This amorphous material was tested without further treatment since extensive hydrolysis was noted with various crystallization techniques. Analytical data for TCM as *N*-( $\beta,\beta'$ -dichlorodiethylaminomethyl)-tetracycline were: theory—(for  $\text{C}_{27}\text{H}_{33}\text{N}_3\text{O}_8\text{Cl}_2$ ) per cent chlorine, 11.85; per cent nitrogen, 7.02; antibacterial assay potency, 760 tetracycline units/mg; found—per cent chlorine, 11.6; per cent nitrogen, 6.3; assay potency 730 tetracycline units/mg. On the assumption of an Einhorn reaction a tentative structure is proposed here.

- (1) *N*-( $\beta,\beta'$ -dichlorodiethylaminomethyl)-tetracycline.  
(2) Epithets: tetracycline mustard, TCM.

Tetracycline mustard was tested under the auspices of the Cancer Chemotherapy National Service Center at Hazleton Laboratories against the *in vivo* mouse tumours sarcoma 180 (S-180), adenocarcinoma 755 (Ca755) and leukaemia 1210 (L-1210). Inhibition of Ca755 was observed at doses of 80 and 60 mg/kg/day (intraperitoneal injections) whereas S-180 was not reproducibly inhibited. Significant prolongation of survival time of mice with L-1210 was noted over a dose range of 80–5 mg/kg/day. Tests against the same tumour types at Bristol Laboratories confirmed these results in every respect. Therapy of mice with L-1210 caused a significant increase in median survival-time over controls (25 per cent or greater) at doses ranging from 80 to 3 mg/kg/day (Fig. 1). These experiments used L-1210 carried in the ascitic form. TCM was not effective against solid trocar implants of L-1210 nor was it effective against ascitic L-1210 if the drug was administered orally at doses up to 180 mg/kg/day. As a control procedure the possibility of carry-over of, or breakdown to, starting reactants was checked biologically. None of the starting materials or formaldehyde reaction products of *nor*HN2 or tetracycline had anti-L-1210 activity at doses within the stoichiometrically equivalent range of effective TCM doses (Table 1). For comparative purposes  $\beta,\beta'$ -dichlorodiethyl-*N*-methylamine (HN2) was tested against L-1210 and found effective at doses of

See legend, Fig. 1. 125 per cent or greater considered 'active'.

1-0.03 mg/kg/day with a maximum increase in survival time of 47 per cent (broken line in Fig. 1). Thus HN2 was almost 100 times more potent than TCM. However, with the curves adjusted so as to be superimposed, the striking similarity of the dose-response is apparent. As a check on stability, tests against *Ca755* were performed with TCM: (1) made up in a single solution which was then refrigerated for two weeks during the period of its use for therapy; (2) prepared fresh daily from the dry powder. The standing preparation seemed to be somewhat more potent than the fresh daily preparation regarding tumour inhibition (for example, *Ca755* was inhibited 77 per cent at 53 mg/kg/day by the standing preparation compared to 42 per cent for a fresh daily preparation).

Since activity of TCM could not be accounted for by its starting materials the remaining possibilities are that either the intact molecule is the active agent or that TCM splits at the amide bond and releases an HN2-like compound. Though no direct chemical evidence is available at present, the following biological data and theoretical

considerations tend to support the latter hypotheses. First, the standing preparation, that is, the material made up once for multiple injection, was more potent than the fresh daily preparation, suggesting instability and breakdown into a more active agent. Second, the dose-response curves of TCM and HN2 were very similar to each other. Third, others have shown that when Einhorn derivatives of tetracycline are subjected to reductive degradation under appropriate conditions, the bridging methylene group remains attached to the amino nitrogen<sup>3,4</sup>.

Obviously the results presented here provide no evidence that TCM accumulates on neoplastic tissue as shown for other tetracyclines. However, if splitting of TCM does occur as described here, it would be of interest to determine whether the hypothesized HN2-like substance is released mostly in the injection solution, the animal's blood stream, or at the neoplastic cell.

### Inhibition of 5-Hydroxytryptamine Liberation from Blood Platelets by Reserpine

RESERPINE causes a release of monoamines from various tissues including isolated blood platelets<sup>1,2</sup>. This effect is generally attributed to an interference of the drug with the storage mechanisms for the amines. Furthermore, some authors report a protective action of reserpine against the spontaneous liberation of norepinephrine from adrenal medullary and splenic nerve granules<sup>3-5</sup>. The mechanism is not fully understood. It might be partly connected with the lack of glucose in the incubation medium, because this source of energy seems to be necessary for retaining the 5-hydroxytryptamine (5HT) within the platelets<sup>6</sup>. We have investigated the effect of reserpine on the metabolism of 5HT of isolated platelets in the absence and presence of glucose.

Fig. 1. *BDF<sub>1</sub>* mice inoculated day 0 with  $1 \times 10^6$  ascitic *L-1210* cells intraperitoneally. Therapy started day 1 intraperitoneally and continued once daily 13  $\times$  or until death of the animal. Survival increase of 25 per cent or greater above control ( $T/C \geq 125$ ) considered effective for inhibition of leukemia growth. All effective doses comprise an average of two or more experiments with at least 6 mice per treatment dose and 10 controls for each experiment. —, TCM; ---, HN2

Fig. 1. Effect of reserpine on the spontaneous 5-hydroxytryptamine (5HT) liberation of platelets pre-incubated and re-suspended in isotonic potassium phosphate, pH 7.5, with or without glucose. Ordinate, 5HT of platelets in per cent of their 5HT content immediately after re-suspension; abscissa, time after re-suspension. The points represent averages  $\pm$  S.E. of 6 experiments. Significance: reserpine 60 and 90 min versus controls:  $P < 0.01$ ; glucose 60 and 90 min versus controls:  $P < 0.01$ ; glucose + reserpine versus reserpine { 60 min  $P < 0.01$ ; 90 min  $P > 0.01$ .

Thrombocytes of rabbits were isolated as previously described<sup>7</sup> and pre-incubated at 37°C for 60 min in isotonic, glucose-free potassium phosphate, pH 7.5, used by previous authors<sup>3</sup>. The centrifuged platelets were then re-suspended in fresh buffer of the same composition and in part supplemented with glucose, reserpine, or glucose + reserpine. Spectrophotofluorimetric measurements of the 5HT of the platelets were carried out during an incubation period of 90 min<sup>8</sup>, and the 5HT metabolites present in the incubation medium were identified by paper chromatography<sup>9</sup>.

In platelets pre-incubated in a glucose-free potassium phosphate medium, the 5HT is rapidly liberated on re-suspension in new buffer of the same composition. This behaviour differs from that under more physiological conditions. Thus, without glucose, platelets lose about 80 and 90 per cent of their 5HT in 60 and 90 min respec-

tively, and no appreciable amounts of 5HT metabolites are present in the buffer (Figs. 1 and 2). The physiological 5HT release, on the contrary, is slow (maximum loss of 5 per cent 5HT within 2 h), and appreciable amounts of 5HT metabolites, especially 5-hydroxytryptophol, appear in the incubation medium<sup>7,9</sup>. The unphysiological liberation of 5HT in glucose-free buffer might be explained by an impairment of the active storage or transport of 5HT in the platelets which seems to depend on supply of energy<sup>6</sup>. Accordingly, supplementation of the buffer with glucose results in a more physiological 5HT liberation, because the diminution of the platelet 5HT is attenuated and 5-hydroxytryptophol reappears in the medium (Fig. 2).

Addition of 1  $\gamma$ /c.c. reserpine to the glucose-free buffer significantly counteracts the spontaneous decrease of the platelet 5HT. After 60 and 90 min respectively, the platelets have lost only about 60 and 75 per cent of their 5HT (Fig. 1). This protective action is dependent on the reserpine concentration, 0.1  $\gamma$ /c.c. causing less, 10  $\gamma$ /c.c. more marked inhibition of the 5HT liberation than 1  $\gamma$ /c.c. In contrast to glucose, reserpine does not restore the metabolism of the 5HT by platelets, because practically no 5-hydroxytryptophol and 5-hydroxyindoleacetic acid are present in the incubation medium (Figs. 1 and 2).

In buffer supplemented with glucose, reserpine no longer inhibits but rather enhances the spontaneous 5HT liberation from blood platelets. In addition, appreciable amounts of 5-hydroxytryptophol are found in the incubation medium (Figs. 1 and 2). This essentially represents the typical pattern of activity of reserpine on platelets suspended in more physiological media<sup>3,7</sup>.

The protective effect of reserpine on the platelet 5HT is thus not observed under relatively physiological conditions. It appears, however, if the active storage mechanism for 5HT is impaired; for example, in a glucose-free incubation medium. Inhibition of the 5HT release from platelets by reserpine does not seem, therefore, to be due to interference with the active storage of the amine. It might rather be the consequence of an action of the drug on the outflux of 5HT through the platelet membrane.

In conclusion, reserpine has probably two separate actions on the platelet 5HT, that is, a releasing effect by interfering with active storage and a protective effect, possibly by decreasing the 5HT outflux through the platelet membrane. In normal platelets with intact storage mechanism, the first action might predominate and conceal the second.

### Anti-viral Activity of Two Guanidine Derivatives in vitro

THE inhibitory properties of guanidine on enterovirus replication have been fully demonstrated<sup>1,2</sup>.

Structural modifications in the guanidine molecule are assumed to cause a marked decrease or a loss of virus inhibiting activity<sup>1,3</sup>. However, in previous publications from these laboratories, we have shown that two guanidine-

Fig. 2. Paper chromatogram of basic extracts of the incubation medium 90 min after re-incubation of isolated blood platelets of rabbits in potassium phosphate buffer, pH 7.5. Solvent system: *N*-propanol-NH<sub>3</sub>, 1 N (5:1 v/v). 1, without glucose; 2, +0.011 M glucose; 3, +0.011 M glucose + 10  $\gamma$ /c.c. reserpine; 4, +10  $\gamma$ /c.c. reserpine; S, standards: A, 5-hydroxytryptamine 3 $\gamma$ ; B, 5-hydroxytryptophol 3 $\gamma$ .

pyrimidines (*N*-2-guanidine-pyrimidine sulphate and *N*-4-guanidine-2,6-pyrimidine sulphate) maintain a high guanidine-like anti-polio activity. Indeed, not only is their antiviral spectrum identical to that of guanidine, but they are also ineffective against guanidine-resistant poliovirus and can replace guanidine in supporting the growth of guanidine-dependent polioviruses<sup>4,5</sup>.

During our investigations on antiviral activity of guanidine-derivatives in order to find some structure-activity relationships, we were able to find that *BW 467C60* (Bethanidine) and its derivative *BW 392C60* were endowed with anti-polio and anti-vaccinia activity *in vitro*.

The viral strains and the procedures used for the culture of human amnion cells (Mascoli's line) were as described previously<sup>6</sup>. The assays of poliovirus cytopathic effect (CPE) were performed by the plaque technique of Dulbecco<sup>7</sup>; those of vaccinia virus CPE were described previously<sup>8</sup>. The inhibition of polio- and vaccinia-virus replication was evaluated by counting the cytopathic units (CPU) present at various intervals in the cell cultures. Since *BW 467C60* and *BW 392C60* lower the pH of the medium, this was kept at 7.3 by adding a few drops of 1 per cent  $\text{NaHCO}_3$  solution.

The data in Tables 1 and 2 demonstrate that the two compounds exert a clear inhibition of the CPE and multiplication of polio and vaccinia viruses.

Table 1. INHIBITION BY BETHANIDINE (467C60) AND ITS O-CHLORODERIVATIVE (392C60) OF POLIO I AND VACCINIA VIRUS CYTOPATHIC EFFECT

Viral strain	Compound tested ( $\mu\text{g/ml.}$ )*	Percentage inhibition (mean and range)
Polio 1	Bethanidine 125.0 (5)	92.2 (75-100)
Polio 1	Bethanidine 62.5 (4)	81.0 (57-96)
Polio 1	Bethanidine 41.0 (2)	3.5 (0-7)
Polio 1	O-Chl. Beth. 125.0 (2)	81.0 (62-100)

Vaccinia	O-Chl. Beth. 62.5 (2)	48.0 (40-56)
Vaccinia	O-Chl. Beth. 41.0 (2)	2.0 (0-4)

\* No. trials in parentheses.

Table 2. INHIBITION BY BETHANIDINE (467C60) OF POLIO I AND VACCINIA VIRUS REPLICATION

Viral strain	Inoculum (CPU)	Bethanidine ( $\mu\text{g/ml.}$ )*	CPU detected after 36 h (mean and range)
Polio 1	$10^4$	— (4)	$5.8 \times 10^7$ ( $6.8 \times 10^6$ – $9.7 \times 10^8$ )
Polio 1	$10^4$	125 (4)	$6.1 \times 10^5$ ( $4 \times 10^5$ – $6.8 \times 10^6$ )
Vaccinia	$5 \times 10^3$	— (4)	$1.5 \times 10^8$ ( $10^8$ – $3 \times 10^8$ )
Vaccinia	$5 \times 10^3$	125 (4)	$1.9 \times 10^4$ ( $6 \times 10^3$ – $3 \times 10^4$ )

\* No. trials in parentheses.

*BW 392C60* and bethanidine seem to act through a different mechanism from that of guanidine.

In fact, (a) the spectra of their virus-inhibiting action differ from that of guanidine, (b) they are fully effective in inhibiting guanidine-resistant poliovirus strains, and (c) they cannot replace guanidine in supporting the growth of guanidine-dependent strains: on the contrary, they inhibit their guanidine-conditioned multiplication.

It appears that antiviral activity is present in several guanidine derivatives, but they seem to exert their inhibiting properties by different mechanisms.

We thank Dr. J. Burns and Dr. R. Kuntzman, Wellcome Research Laboratories, for a supply of bethanidine and O-chlorobethanidine. This work was supported by the NATO research grant *Scm* 5-2-05 (164)/1802 (63).

### Bronchoconstrictor Action of Bradykinin, Kallidin and Eledoisin

COLLIER *et al.*<sup>1</sup> reported in 1959 that partially purified natural bradykinin, made by incubating trypsin with ox globulin, causes bronchoconstriction when injected into guinea-pigs. This action was confirmed for the synthetic nonapeptide<sup>2,3</sup> as well as for the decapeptide kallidin<sup>4</sup> and the endecapeptide eledoisin<sup>5</sup>. In contrast to the bronchoconstrictor action of serotonin and histamine, the effect of bradykinin and kallidin was completely abolished by pretreatment with acetylsalicylic acid and phenylbutazone<sup>1,4</sup>.

These experiments were carried out in artificially respired guinea-pigs using the sensitive overflow method of Konzett and Rössler<sup>6</sup>. In spontaneously respiring guinea-pigs, however, we found that doses of bradykinin and kallidin up to 16  $\mu\text{g/kg}$  (intravenous) did not decrease but rather increased the respiratory minute volume by more than 100 per cent<sup>7,8</sup>, while higher doses (20–60  $\mu\text{g/kg}$ ; intravenous) produced apnoea which is probably of central origin<sup>9</sup>.

In the experiments to be described the actions of synthetic bradykinin and kallidin on tidal volume and on inflation volume were examined in guinea-pigs under urethane anaesthesia by means of body-plethysmography according to the method of Koller<sup>10</sup>; the effects were compared with those of eledoisin and serotonin. All injections were made through a cannula in the external jugular vein.

In spontaneously breathing guinea-pigs graded doses of serotonin and eledoisin produced a dose-dependent reduction of the tidal volume (Fig. 1). Furthermore, a tachypnoic response of short duration was regularly observed. Following the injection of high doses of serotonin (10  $\mu\text{g/kg}$ ) and of eledoisin (5  $\mu\text{g/kg}$ ), the tidal volume became virtually zero although the movements of the respiratory muscles (Fig. 1, bottom trace)<sup>11</sup> had increased. Bradykinin, however, reduced the tidal volume only slightly in doses up to 20  $\mu\text{g/kg}$  and caused a long-lasting tachypnoea, while higher doses (25  $\mu\text{g/kg}$ ) produced an arrest of respiration in expiratory position. Similar results were obtained with kallidin.

In artificially respired guinea-pigs serotonin and eledoisin reduced the inflation volume by an amount depending on the given dose (Fig. 2). To reduce the inflation volume by 50 per cent ( $ED_{50}$ ) approximately 1  $\mu\text{g/kg}$  of eledoisin and 9  $\mu\text{g/kg}$  of serotonin were required. The dose-response curve of bradykinin differed from those of eledoisin and serotonin by its slope. 1  $\mu\text{g/kg}$  of bradykinin had nearly

Fig. 1. Effect of bradykinin, eleodoin and serotonin on the tidal volume in the guinea-pig. Guinea-pig (420 g) under urethane anaesthesia (1.5 g/kg; subcutaneous). Body-plethysmography; for details of method see Gjuriš *et al.*<sup>4</sup>. Bottom trace: movements of respiratory active muscle groups

maximal effect, and even extremely high doses (up to 200 µg/kg) were unable to reduce the inflation volume by more than 50 per cent. The dose response curve of the less-active kallidin closely resembled that of bradykinin.

The reduction of inflation volume by small doses of bradykinin and kallidin (5 µg/kg) was completely prevented by the broncholytic agents isoprenaline (1–10 µg/kg) or epinephrine (0.5–10 µg/kg). High doses of the plasma kinins (50 µg/kg), although not significantly more effective, remained unaffected or were only slightly reduced by the broncholytics which, on the other hand, readily abolished even the maximal effects of eleodoin or serotonin.

Acetylsalicylic acid (5–10 mg/kg) and phenylbutazone (5–10 mg/kg), which did not prevent the reduction of inflation volume caused by eleodoin or serotonin, abolished only the action of small doses of bradykinin and kallidin (5 µg/kg), but did not antagonize the action of higher doses of the plasma kinins (50 µg/kg). Even pretreatment with 100 mg/kg of acetylsalicylic acid failed to prevent the action of 50 µg/kg of bradykinin or kallidin.

The different slopes of the dose-response curves of bradykinin and kallidin as compared with those of eleodoin and serotonin suggest that the action of the plasma

kinins cannot be explained simply by bronchoconstriction. Since the pleura of the guinea-pig's lung contains an exceptionally large number of smooth muscle fibres<sup>11</sup>, it seems possible that the reduction of inflation volume caused by the plasma kinins is at least partly due to the contraction of pleural muscle fibres. This view is supported by the finding that bradykinin is much more effective in reducing the inflation volume when applied locally to the pleural surface instead of being administered by inhalation or by intravenous injection, while the reverse holds true for histamine<sup>4,12</sup>.

Recently, it has been reported<sup>13,14</sup> that in guinea-pigs small doses of the plasma kinins produce constriction of pulmonary vessels (possibly of the pulmonary veins) which was also prevented by salicylates. Thus, an increased blood volume of the lungs as caused by the constriction of pulmonary veins might be an additional factor in the action of the plasma kinins.

Fig. 2. Effect of bradykinin, eleodoin and serotonin on the inflation volume in guinea-pigs. Body-plethysmography in guinea-pigs (350–520 g) under urethane anaesthesia (1.5 g/kg; subcutaneous). Artificial respiration with a Starling pump (40 strokes per min) at constant pressure (100 mm H<sub>2</sub>O). Paralysis of the respiratory muscles with succinylcholine (0.2 mg/kg; intravenous) 1 min before the intravenous injection of bradykinin, eleodoin and serotonin resp. Inflation volume before the injection of the bronchoconstrictor agents was assumed to be 100 per cent. Each point represents the mean  $\pm$  S.E. of 6–13 experiments

THE interesting observation of Gjuriš and Westermann that bradykinin differs from 5-hydroxytryptamine in its action on the tracheobronchial muscle of the guinea-pig accords with previous findings. For example, Jänkäälä and Virtama<sup>1</sup> concluded from radiography that 5-hydroxytryptamine "causes vigorous constriction of all the constrictable bronchial tree of the guinea-pig", whereas "bradykinin apparently only affects the respiratory bronchioles". I am glad that Gjuriš and Westermann support the suggestion we made some time ago<sup>2</sup>, that bradykinin may also affect the smooth muscles of the pleural surface of the lung.

Since bradykinin probably acts on a smaller part of the bronchial tree than does 5-hydroxytryptamine, it cannot be expected to reduce to the same extent the volume of air entering the lungs. In our hands, intravenous doses of 8 or more µg/kg of bradykinin usually reduce by > 50 per cent the inflation volume of a guinea-pig, which is artificially ventilated after suppression of spontaneous respiration with urethane. The difference from the 40 per cent reduction obtained with 50–200 µg/kg of bradykinin by Gjuriš and Westermann (Fig. 2) may perhaps arise from the fact that repeated doses of bradykinin readily cause refractoriness of the bronchoconstrictor response<sup>3</sup>. Repeated doses of 5-hydroxytryptamine, on the contrary, often elicit successively larger responses.

Such changes of sensitivity are particularly likely to intrude when many doses are given in obtaining a dose-response curve.

The failure of Gjuriš and Westermann to 'antagonize' the bronchoconstrictor action of a large intravenous dose of bradykinin (50 µg/kg) with a still larger dose of aspirin (100 µg/kg) only partly accords with our observations<sup>4</sup>. We found that, within the intravenous dosage range of 0.5–8 mg/kg of aspirin, the ratio of this drug to bradykinin required to yield a constant response is roughly constant. Increasing the dose of aspirin above 8 mg/kg does not proportionately increase the antagonism. An intravenous dose of 8–16 mg/kg of aspirin, however, greatly reduces the bronchoconstrictor response to 32 µg/kg of bradykinin and makes the response to 100 µg/kg of bradykinin about the same as that to 1 µg/kg without aspirin. This action of aspirin is local, since it occurs after destroying the spinal cord and cutting the autonomic nerves to the lungs<sup>5</sup>.

The finding of Gjuriš and Westermann that isoprenaline fails to antagonize bronchoconstriction induced by large doses of bradykinin agrees neither with our experience nor with their own previous statement<sup>6</sup>.

Since, in at least some of their experiments<sup>7,8</sup>, Gjuriš and Westermann have used bradykinin supplied in ampoules, a further possible source of difference from those who have derived their bradykinin solutions directly from the pure synthetic solid should be considered. Chlorbutol, which is sometimes present in ampoules of bradykinin at a concentration of 5 mg/ml., diminishes the amplitude of inspiration in both dog and rabbit, according to Impens<sup>9</sup>. Although the doses he used were relatively large, they were given by mouth, and the possibility must therefore be considered whether smaller doses of chlorbutol, injected into blood vessels along with bradykinin, might themselves affect respiration, especially if respiratory depressants such as urethane had previously been given.

## HAEMATOLOGY

### Detection of Catalase after Electrophoresis of Hæmolysates on Starch Gel

CATALASE, a hæmoprotein normally present in erythrocytes, can be separated from hæmoglobin by electrophoresis of hæmolysates on starch gel. The production of gas bubbles with hydrogen peroxide, and enzyme assays of eluates from segments of the gel, have shown that, after electrophoresis, erythrocytic catalase is confined to one discrete zone<sup>1</sup>. This zone stained weakly with naphthalene black, but, with benzidine or *o*-tolidine, showed a strong colour reaction, similar to the colour produced in the hæmoglobin zones. Owen, Silberman and Got<sup>2</sup> found that *o*-dianisidine was the most satisfactory reagent for the detection of hæmoglobin and of hæmoglobin-haptoglobin complexes on starch gel. The use of *o*-dianisidine as a stain for catalase on starch gel has been investigated, and it has been found that, under certain conditions,

a differential colour staining can be obtained, catalase being green and hæmoglobin brown.

After separation of plasma from heparinized blood, erythrocytes were washed three times with cold isotonic saline, and hæmolyzed by freezing and thawing twice. The hæmolysate was diluted by the addition of 0.5 volume of water and then was shaken up with 0.5 volume of carbon tetrachloride. The aqueous layer was removed and centrifuged at 4° C and 55,000*g* for 60 min. Finally, the hæmoglobin content was adjusted to 15 g/100 ml. by the addition of water. Starch-gel electrophoresis was based on the method of Smithies<sup>3</sup>. Hydrolysed starch (Connaught Medical Research Laboratories, Toronto) was used in a concentration of 14 g/100 ml. buffer. A *tris*-citrate-borate buffer system was used at pH 9.5, as these conditions were found to provide the best separation of the non-hæmoglobin erythrocytic proteins<sup>1</sup>.

The reagents for the *o*-dianisidine stain were: *o*-dianisidine, 0.3 g in 100 ml. methanol; acetate buffer, pH 4.6, prepared by mixing 1.5 M acetic acid solution with 1.5 M sodium acetate solution; hydrogen peroxide solution, 100 vols; 'Teepol' (Shell Chemical Company, Ltd.), 1:250 dilution in water. The most satisfactory method was found to be as follows. Fifty ml. of the dianisidine solution and 50 ml. of the acetate/acetic acid buffer were mixed and 0.4 ml. H<sub>2</sub>O<sub>2</sub> (100 vol.) added just before use. The gel was flooded with this mixture until the hæmoglobin stained dark brown (5–10 min). After pouring off the staining solution and washing with 1:250 'Teepol' solution the gel was then allowed to stand for several hours in the 'Teepol' solution. Within a few minutes of the addition of the 'Teepol', a faint green colour was apparent in the solution, and this colour gradually increased in intensity. The green staining of the catalase zone did not appear immediately, but only after standing in the 'Teepol' solution for a few hours. The hæmoglobin zones were then purplish-brown, and no area of the gel showed any green stain except the catalase zone (Fig. 1). The differential staining did not depend on the different concentrations of peroxidatic substance, as hæmoglobin did not stain green by this method after electrophoresis of a series of dilutions of hæmolysates with hæmoglobin concentrations ranging from 15 g/100 ml. to 0.015 g/100 ml.

Best results were obtained with 1:250 'Teepol' solution, but green colouring of the catalase zone also occurred, more slowly, and less intensely, with other dilutions of 'Teepol' within the range 1:25 to 1:2,500. With weaker 'Teepol' solutions or when distilled water was used alone following staining with *o*-dianisidine, no green colour developed. Also, green did not appear with a stronger 'Teepol' solution (1:10).

The concentration of *o*-dianisidine in methanol was not critical and green staining of catalase occurred with *o*-dianisidine solutions from 0.1 to 1.0 per cent provided the time of staining was adjusted so as to avoid excessive staining of the hæmoglobin zones. Optimum results were obtained by staining with 0.3 g *o*-dianisidine in 100 ml. methanol for 5–10 min.

On varying the molarity of the acetic acid/acetate buffer, at pH 4.6, similar differential staining was produced using buffers in the range of 0.75 M–1.5 M. Less distinct colour differentiation occurred with molarity of 3.0 and a green colour was not consistently produced with buffer more dilute than 0.75 M. When acetic acid/acetate buffer, 0.75 M, was used in a range of pH values from 3.25 to 5.90, similar green colouring occurred with buffer of pH 4.80 or less but no green appeared with buffer of higher pH. The most satisfactory results were obtained with acetic acid/acetate buffer, 1.5 M and pH 4.6.

After electrophoresis of an aqueous solution of bovine liver catalase (Mann Research Laboratories, New York) (20 mg/ml.), on starch gel, at pH 9.5 under the same conditions as for hæmolysates, the main catalase zone (corresponding to the area of gas bubbles when hydrogen peroxide was applied to the gel) stained green with

Fig. 1. Starch-gel electrophoresis of a normal hemolysate. A, Stained with dianisidine. The hemoglobins ( $A_1$  and  $A_2$ ) stained brown, whereas catalase (non-hemoglobin protein zone III) stained green; B, stained with amido-black, showing the hemoglobins and the non-hemoglobin proteins (NHP zones I-IV, following the nomenclature of Haut *et al.*)

*o*-dianisidine. Horseradish peroxidase (Mann Research Laboratories, New York), on electrophoresis of an aqueous solution (0.4 mg/ml.) at pH 9.5, showed separation into at least eight zones—two anodal and six cathodal to the origin. When the gel was stained with *o*-dianisidine these zones transiently became bright green, and within a few minutes the colour had changed to chocolate-brown.

A method for the localization of catalase on starch gel, based on the oxidation of iodide to iodine by hydrogen peroxide with subsequent staining of the starch gel except in the area of  $H_2O_2$  destruction by catalase, has been described<sup>4</sup>. This method distinguishes catalase from other hydro-peroxidases, but the area showing the catalase reaction is more diffuse than with the *o*-dianisidine stain and overlaps several non-hemoglobin protein zones in the electrophoretic pattern of normal hemolysates<sup>1</sup>.

The *o*-dianisidine method produces the staining reaction as a result of the peroxidatic activity of catalase, and of hemoglobin, catalysing the oxidation of *o*-dianisidine to a coloured compound. When the hemoglobin concentration in hemolysates is greatly reduced by dilution, electrophoresis and staining with *o*-dianisidine results in the same colour of the hemoglobin zones as with the more concentrated solutions, so that the green colour of the catalase zone is not due solely to reduced concentration of peroxidatic material compared with the hemoglobin zone.

The appearance of green colour in the supernatant 'Teepol' solution before the catalase zone itself stains green and the relatively slow development of the green catalase zone suggest that the green pigment is formed from the *o*-dianisidine by the action of 'Teepol' and then is selectively absorbed into the gel in the position of the catalase. The explanation of the different colours produced with the catalase and hemoglobin with *o*-dianisidine is not clear, but it affords a convenient method of localizing catalase on starch gel, and of distinguishing it from hemoglobins.

I thank Mr. D. Gow and Mrs. E. Smith for their help.

## Presence of Two $Ph^1$ Chromosomes in Cells from a Patient with Chronic Granulocytic Leukaemia

THE 'Philadelphia' chromosome first described by Nowell and Hungerford<sup>1</sup> is characteristic of chronic granulocytic leukaemia and can be demonstrated in the myelocytic cells of most cases.

In typical cells only one  $Ph^1$  chromosome is present. Recently a number of cases with cells containing two  $Ph^1$  chromosomes have been described<sup>2,3</sup>. In most of these the finding has been made in the acute blast stage of the disease or shortly before this change has occurred. This might suggest that the finding, like that of aneuploidy with more than one cell line, is a sign of impending if not actual 'blastic crisis'.

We report here a case of chronic granulocytic leukaemia with cells showing two  $Ph^1$  chromosomes in direct bone marrow preparations. Five months later the patient still shows the features of chronic granulocytic leukaemia with no evidence of morphological or clinical change in the disorder.

Fig. 1. Karyotype of cell from bone marrow of J. V., with 48 chromosomes. Group G contains six chromosomes of which two are  $Ph^1$  chromosomes

J. V., a male born in 1900, was diagnosed as having chronic granulocytic leukaemia in January 1963. He was initially treated with busulphan. In May 1963 thrombocytopenia developed and he was referred to one of us for an opinion as to further therapy. Busulphan therapy was ceased and steroids were given with a good platelet response. In February 1964 he was seen again with a rising white cell count. The haemoglobin was at a satisfactory level and, as he was well, no therapy was advised. A bone marrow specimen was taken at this time and showed the features of chronic granulocytic leukaemia. Cytogenetic material was prepared directly from this specimen of marrow.

Results from investigation of these preparations are shown in Table 1. A karyotype of a bone marrow cell showing two  $Ph^1$  chromosomes is illustrated in Fig. 1.

In June 1964 the patient was seen again. The spleen was enlarged and the white cell count had risen further. A course of splenic irradiation was given with a good therapeutic result.

The presence of two  $Ph^1$  chromosomes in this case suggests that the finding is a variant of the usual picture in chronic granulocytic leukaemia. Since it can be found

Table 1

Type of preparation	Date	Haematological findings	Treatment	Total No. cells	46	47	48	Tetra-ploid
Direct bone marrow	3.2.64	Hypercellular marrow with characteristic features of chronic granulocytic leukaemia	Busulphan from 11.1.63 to 22.5.63	50	15 (14 $Ph^1$ +)	34 (32 $Ph^1$ +)	1	1

Of the 15 metaphases with 46 chromosomes, 14 showed the  $Ph^1$  chromosome. Of the 34 metaphases with 48 chromosomes, 32 showed 2  $Ph^1$  chromosomes, and the remaining 2 showed a single  $Ph^1$  chromosome.

in the chronic phase of the disease it is of no prognostic significance.

## PATHOLOGY

### Drug-induced Regression of Large Plasma Cell Tumours

WHILE many transplanted animal tumours may be cured if treated with chemotherapeutic agents the day after implantation, there are few reports of the regular cure of such tumours if treatment is delayed until the tumours are advanced and large (that is, more than 20 per cent of the body-weight). This communication reports the regular cure of large, well-established mouse plasma cell tumours (*ADJ-PC5*) (ref. 1) up to 21 days old and 5 g in weight with a single intraperitoneal dose of *N,N*-di-2-chloroethyl aniline (aniline mustard, *CB 1074*) (I).

The high activity of aniline mustard against this tumour was first observed in an examination of the tumour as a screening test for chemotherapeutic agents likely to be of value in the treatment of multiple myeloma in man<sup>2</sup>. Tested against 10-day implants weighing about 0.1 g, aniline mustard proved to have a more selective inhibitory effect than a number of agents in clinical use, such as *cyclophosphamide* and *melfalan*. When more advanced tumours were used, namely, 17–21 days after implant, aniline mustard still gave complete regression of the tumours at a dose of 40 mg/kg, that is, one-third the *LD*<sub>50</sub>. None of the early symptoms usually associated with nitrogen mustard toxicity was seen at this dose but some late deaths occurred after regression was complete. A dose of 60 mg/kg, however, which did not harm normal mice, killed 30 per cent of mice bearing 21-day tumours and 90 per cent of those bearing 25-day tumours. The results of some typical experiments are shown in Table 1. Tumour-weight was estimated from caliper measurements using a standard curve obtained experimentally<sup>3</sup>. Tumour-weights thus obtained ranged from 1.1 g to 5.1 g on the day of treatment. Regression occurred very rapidly during the first week, then much more slowly (Fig. 1). Mice were usually killed at the 50th day, but those of

Fig. 1. Representative growth and regression curves of *ADJ-PC5* implants given *CB 1074* 18 days after implantation

experiment IV have now been kept for 140 days and no recurrence can be found by palpation.

Sugiura and Stock<sup>3</sup> have reported the cure of a number of 7-day-old mouse and rat tumours, and complete regression of 21-day-old Flexner-Jobling carcinomas in rats was obtained with a single dose of OPSPA by Heidelberger and Baumann<sup>4</sup>. Long survival of another mouse plasma cell tumour, *YPC-1*, given courses of *cyclophosphamide*, beginning day 16, has recently been reported<sup>5</sup>.

The reason for the high selectivity of aniline mustard requires further investigation. It is certainly closely related to the structure of the alkylating agent since the *p*-methyl derivative (III, *CB 1044*) caused little inhibition of the growth even of 10-day *ADJ-PC5* implants, while *p*-methoxy aniline mustard (II, *CB 1045*) appears to be somewhat more effective than the unsubstituted compound, causing, in a recent experiment, complete regression in three out of four 27-day tumours having a mean weight of 7 g at the time of treatment. It is possible that *p*-hydroxylation by the tumour is required for selective action, and investigations of this possibility are in progress.

The mechanism of cure of mice bearing large tumours has been investigated, notably by Martin<sup>6</sup>. This and other work<sup>7,8</sup> suggests that a specific host response may be necessary for cure to occur. The *ADJ-PC5* tumour is carried in the isologous host, and in more than 300 implants allowed to grow for 20 days no spontaneous regressions were observed. That an immune mechanism is active in our tumour system was, however, revealed by re-implantation of 12 of the mice of experiment IV, 100 days after the original treatment with aniline mustard. Only one-third of the second implants were palpable at 23 days, and the mean size was only 0.25 g compared with 3.3 g in the control group.

### Gamma-glutamyl Transpeptidase in Cancers of Different Human Organs

In 1961 we published<sup>1</sup> a method for the histochemical localization of  $\gamma$ -glutamyl transpeptidase (GGTP) in the organs of experimental rodents and in man. Independently, a few months later, similar results were reported by Glenner, Folk and McMillan<sup>2,3</sup>, who in contrast to our findings<sup>1,4</sup> also discovered GGTP activity in the bronchi and bronchioles of the rat.

In 1962, at the seventh International Cancer Congress in Moscow, we exhibited photomicrographs indicating the GGTP distribution in renal cancer in man<sup>5</sup>. The activity of the enzyme was found in the cells of solid cancer and of that consisting of glandular tubules. Using the biochemical method<sup>6</sup> we were able to establish that the GGTP content in renal cancer is about 10 times less than in the normal kidney<sup>5</sup>. Recently we realized that in Wilms's tumour (nephroblastoma) the cells lining the canalicular lumen showed GGTP activity.

Then we proceeded to the examination of GGTP activity in other tumours in man: these included sarcomas and cancers of various organs. We found that only cancers originating from organs exhibiting normal GGTP activity contained the enzyme; thus, GGTP activity could be detected in cancers of the hepatic cells, of the mucous membrane of the uterus, of the pancreas, breast or prostate, whereas none was exhibited by cancers taking their origin from the epidermis, the multilayered flat epithelium of the larynx, or the vaginal part of the uterus and bladder; it was also absent in sarcomas.

Table 1. GAMMA-GLUTAMYL TRANSPEPTIDASE ACTIVITY IN PRECANCEROUS LESIONS, BENIGN AND MALIGNANT TUMOURS OF THE BREAST

Histological diagnosis	Mean activity in units	
	Per 1 g of tissue	per 1 g of protein
Normal woman breast	0.290 $\pm$ 0.081	0.0028 $\pm$ 0.0003
Breast cancer	0.259 $\pm$ 0.049	0.00200 $\pm$ 0.0003
Mastopathia	0.321 $\pm$ 0.197	0.0024 $\pm$ 0.0016
Fibroadenoma	0.357 $\pm$ 0.036	0.00305 $\pm$ 0.0004

An observation, related to GGTP activity, might help in the histological diagnosis of some cancer cases. Post-mortem histological examination in a case of pancreatic cancer showed in the omentum the presence of cell infiltrates which could not be identified as being of cancerous or inflammatory nature. As the cells of pancreatic cancer contain a clear-cut GGTP activity the omentum infiltration was examined from this point of view. The omentum cells showed a conspicuous GGTP activity, thus pointing to the existence of metastatic lesions and not to the inflammatory reaction. This method supplements staining techniques for the detection of mucus in the diagnosis of cancer originating from the glandular epithelium.

As to renal tumours, GGTP activity of the cancers was lower than that of organs from which they came. Using bioptic intraoperative specimens, we have investigated cancers, fibro-adenomas and mastopathia cystica of the breast in women. It has been found that GGTP values in normal breast exceeded those found in cancers, but in fibro-adenomatous mammae and in cases of mastopathia cystica they were still higher than in the normal organ (Table 1).

### Kinetics of Cellular Growth after Repeated Applications of Methylcholanthrene

EARLIER I reported my examinations on variations in the mitotic duration, mitotic count, and mitotic rate after a single surface application of methylcholanthrene to mouse skin<sup>1</sup>. It was found desirable to continue these studies after repeated paintings inasmuch as continuous painting is followed by hyperplasia and tumour formation, and the present communication concerns an investigation of the mitotic rate during a period of additional and excessive growth. Hairless mice (*hr/hr*) were painted 3 times weekly with 0.6 per cent solution of methylcholanthrene in benzene. Each week one group of eight mice was killed, the last group 13 weeks after the first application. Mitoses were counted, the mitotic duration was estimated by the 'Colcemid' method, and the rate calculated according to the equation: (mitotic duration)  $\times$  (mitotic rate) = mitotic count (ref. 2).

The first tumours appeared after some 6 weeks, and after 10 weeks all the remaining animals had one or several manifest carcinomas in the treated area. The results are shown in Fig. 1 and Table 1.

Table 1. CHANGES IN EPIDERMAL MITOTIC COUNT, MITOTIC DURATION, AND MITOTIC RATE AFTER REPEATED APPLICATION OF 0.6 PER CENT METHYLCHOLANTHRENE

Time (weeks)	Mitotic count (per 6 mm)	Mitotic duration (h)	Mitotic rate (per 6 mm/h)
1	15.8 $\pm$ 4.6	3.1	5.2
2	19.0 $\pm$ 2.2	2.6	7.5
3	15.5 $\pm$ 1.7	1.9	8.3
4	16.5 $\pm$ 3.0	1.6	10.4
5	18.3 $\pm$ 1.7	1.8	10.0
6	26.0 $\pm$ 3.5	1.9	13.7
7	22.3 $\pm$ 4.1	2.3	9.9
8	38.0 $\pm$ 7.7	1.8	21.1
9	28.5 $\pm$ 2.6	2.6	10.9
10	40.3 $\pm$ 7.1	2.9	13.9
11	30.3 $\pm$ 7.1	2.8	10.7
12	29.0 $\pm$ 8.5	2.2	13.1
13	22.8 $\pm$ 4.2	3.0	7.6

The mitotic counts represent the means of groups of four mice. The mitoses in 6 mm epidermis were counted in each specimen. The mitotic duration and rate represent the means of observations on 8 mice; four killed before, and four after a delay of 4 h after injection of colcemid.

The experiment shows that the highly increased mitotic count during the first weeks is exclusively due to prolonged mitotic duration. The mitotic rate is lower than normal in this period and only from about the 5th week is the rate slightly increased. Incidentally, the mitotic duration after 13 weeks, in the skin between the tumours, was the

Fig. 1. Variations in mitotic count, mitotic duration, and mitotic rate after repeated applications of 0.6 per cent methylcholanthrene

same as in the spinocellular induced carcinoma in a hairless mouse reported by Evensen and Iversen<sup>3</sup>.

Again it is seen that an increased number of mitoses is not synonymous with a high rate (defined as the number of mitoses completed per unit time). The findings are fully in accordance with those observed immediately after application of different carcinogens to the epidermis of mice<sup>4</sup>. The results also offer an explanation for the discrepancy between the high number of mitoses and the moderate growth rate of some tumours observed by earlier authors<sup>5,6</sup>.

According to the findings reported here the carcinogens, as represented by methylcholanthrene in the present experiment, do not as such 'stimulate' the mitotic rate. The explanation of the hyperplasia thus has to be sought in a different way.

### Causative Agent of a Spontaneously Originating Visceral Tumour in the Newt, *Triturus*

A SPONTANEOUS visceral tumour was found about ten years ago by one of us in the Japanese newt, *Triturus pyrrhogaster*<sup>1</sup>. The original animal showed a number of tumorous nodules in the liver and spleen ranging in size from tiny ones to the largest measuring 1.1 cm × 0.7 cm × 0.4 cm. The tumour was transplanted through many generations to other *pyrrhogaster*; and it was classified as a lymphosarcoma on the basis of its histogenesis after transmission<sup>2</sup>. It may be transmitted not only to *pyrrhogaster* but also to other species of newts and salamanders<sup>3</sup> and, as we have found recently, to the adult anuran, *Xenopus laevis* (unpublished). Moreover, the supernatant of tumour homogenates retained the capacity to produce tumour even after the homogenates were frozen and thawed and dried *in vacuo*. Evidence presented here points to a bacterium as the likely agent.

Electron microscopical observations were made on excised tissue fixed in 1 per cent osmic acid or osmic acid-sucrose solution buffered at pH 7.5 for about 1.5 h and embedded in butyl methyl methacrylate mixture (7:3) or in 'Epon'. They showed numerous intracytoplasmic oval or rod-shaped bodies the structure of which is consistent with that of bacteria<sup>4-6</sup>. The inclusions were approximately 0.22–0.45  $\mu$  wide and up to 2.0  $\mu$  long; they were provided with a cell wall of two concentric layers surrounded by an amorphous, presumably capsular material of variable thickness (Fig. 1). Internal to the cell walls is an area, presumably cytoplasmic, showing low-density inclusions and, centrally placed, a light region containing a meshwork of fine threads, presumably the nucleus.

Histological and cytological investigations were made of tumour tissue and of smeared filtrates of tumour and normal liver homogenates passed through a 3.0  $\mu$  'Millipore' filter. Smear preparations—dried, heat-fixed and stained with Giemsa, periodic acid-Schiff or iron haematoxylin—showed, in the case of tumour homogenates, bacterial-like bodies of about the size seen in electron microscopic preparations. They were oval or rod-shaped and occurred singly, in pairs, clusters, or sometimes in chains. They were not found in similarly prepared smears of normal liver.

Histological sections (3  $\mu$ ) of tumorous liver after fixation in osmic acid and paraffin embedding showed a faint

Fig. 1. Electronmicrograph showing bacterial organism in cytoplasm of tumour cell of *T. pyrrhogaster*. Note voluminous capsular substance (S), typical bacterial cell wall (W) composed of two layers, cytoplasmic area (C) and inclusions, and light nuclear area (N) with a meshwork structure ( $\times 48,800$ ).

Feulgen reaction for deoxyribose nucleic acid in the cytoplasmic granules, which also stained with the Giemsa dye and with iron haematoxylin. The granules also were acid-fast as demonstrated in sections (5  $\mu$ ) of tumorous liver fixed in Helly's fluid, stained with carbolfuchsin, decolorized in 95 per cent ethyl alcohol containing hydrofluoric acid (3 per cent), and counter-stained with methylene blue.

*T. pyrrhogaster* carrying the tumour were injected subcutaneously with four successive doses of 16  $\mu$ c. of tritiated thymidine in 0.15 ml. of saline solution at intervals of 2 h. Four hours after the final injection, the liver was excised and fixed in 1 per cent osmic acid-sucrose solution. After sectioning at 3  $\mu$ , the specimens were stained with Feulgen reagent and coated with Kodak nuclear track emulsion, 'NTB3'. The coated slides were developed after 21 days at 2° C. The sections showed incorporation of radioactive thymidine in the cytoplasm as well as in the nucleus of tumour cells. Liver parenchyma and non-tumorous areas of the capsule showed no cytoplasmic incorporation.

Bacteriological investigations were undertaken in which the tumorous liver and spleen of two newts, one *T. pyrrhogaster* and one *T. viridescens*, were removed under sterile conditions, and ground in sterile mortars and pestles containing 4 ml. tryptose phosphate broth; 0.01 ml. of the homogenates was planted on the following media and then incubated aerobically or anaerobically at 22° C: tryptose blood agar base containing 5 per cent sheep blood; Mueller-Hinton agar; and Endo agar. Within two days 5–20 colonies of several species of Gram-negative bacilli were isolated which, because of their variety and low numbers, were regarded as autopsy contaminants. Numerous tiny colonies appeared after 10 days aerobically at both temperatures on blood agar and Mueller-Hinton agar. Microscopic observations showed slender, irregularly staining Gram-positive bacilli reminiscent of similarly stained human tubercle bacilli. The

organisms were solidly acid fast after the cold acid fast technique using 'Tergitol 7' and 3 per cent acid alcohol. Sub-culture in 'Tb' broth (Difco) medium containing 'Tween 80' gave in each case good growth in 4 days at 22° C, but growth in Lowenstein-Jensen's medium required about 3 weeks. The procedures of plating and sub-culturing were repeated at least four times for each of the cultures. The liver and spleens of four uninoculated control newts, two of each species, were similarly removed, ground, and planted in 'Dubos Oleic' agar (Difco) at both temperatures; the cultures were negative after six weeks of incubation.

Four *T. pyrrhogaster* and four *T. viridescens* were respectively injected intraperitoneally with 0.3 and 0.2 ml. each of a heavy serially cultured 'Tb' broth of the acid-fast bacterium. Gross observations after 5-14 weeks showed disseminated nodules of the liver and spleen resembling those induced by intraperitoneal tumour transplants. Smears of the organ or of ground samples revealed large numbers of acid-fast bacilli. When cultured, these organisms were identical with those isolated originally. Histological examinations of these bacterially induced growths showed cell masses in the liver and spleen with the same histological characteristics of the original tumour, namely, masses of mononuclear cells of the capsule invading the parenchyma of the liver. Bacterial cultures which yielded tumours in 3 *T. pyrrhogaster* and 3 *T. viridescens* were also made on Sabouraud's dextrose agar; but these cultures were not pursued through serial passage.

The histopathological response to the injected culture is being investigated further and assessed against the background of opinions now prevailing on granulomatous and sarcomatous diseases. The ensemble of evidence at the moment shows that the tumour cells, first found in the Japanese salamander and transmitted through many generations, contain a bacterium; that cultures of the organism yield a response which resembles closely the response induced by tumour transplants or by injections of tumour homogenates; and, therefore, that the bacterium or some causative factor associated with the bacterium may be the agent of the tumour. Organisms, similar to that which we have described, have been isolated and cultured from tumours and blood of tumorous mammals including man<sup>7,8</sup>, and injection into mice and guinea-pigs has been reported to yield a chronic granulomatous disease or neoplasms<sup>7,8</sup>. In the case of plants, ample proof and experimentation have been published to show that the crown gall is bacterial in origin<sup>9</sup>.

This work was supported by grants from the American Cancer Society and the U.S. National Institutes of Health. We are grateful to Prof. R. F. Parker of the Department of Microbiology and the Institute of Pathology for his guidance in the bacteriological work.

## IMMUNOLOGY

### Comparison of Tumour Antigens in AKR and Gross Virus (Passage A)-induced Leukaemias

EARLIER experiments have shown that it is possible to characterize the group of lymphomas elicited by Gross Passage A virus using immunological methods. It was shown that a resistance to tumour transplantation could be developed in mice by administering low doses of tumour cells; this effect was obtained in both the syngeneic and the allogeneic tumour-host system<sup>1</sup>. Serum from immunized mice exerted a cytotoxic effect on transplanted Gross tumour cells *in vitro* in the presence of complement<sup>2</sup>. Individually induced Passage A tumours were found to cross-react, whereas tumours induced by other means did not. Cross-reactivity was demonstrated for Gross tumour cells by (a) ability to induce and sensitivity to transplantation resistance, (b) ability to induce and sensitivity to cytotoxic antibodies, (c) specific absorption of cytotoxic antibodies by tumour cells, and (d) specific tumour cell neutralization by immune lymph node cells.

It was concluded that the group of tumours produced by Passage A virus possessed a specific antigen different from normal tissue antigens and other tumour antigens. Using the cytotoxic technique, this antigen could be detected *in vitro*.

The Gross Passage A virus was originally isolated from a spontaneous leukaemia of an AKR female<sup>3</sup>. The AKR mouse strain has been inbred with the aim of producing a high leukaemia mouse strain. They develop a lymphatic leukaemia spontaneously and at a high rate at 6-8 months of age.

The isolated agent was found to produce leukaemias in certain low-leukaemia mouse strains also, for example, when inoculated into new-born animals of C3H/BI or C57BR/cd origin. After several passages in new-born mice, the potent Passage A virus was obtained, which produced lymphatic leukaemias at a high frequency and after a relatively short latency period (3-4 months) in those low-leukaemia strains<sup>4</sup>.

In view of the fact that Passage A virus was originally derived from AKR mice, we found it promising to compare AKR leukaemias with Passage A virus-induced leukaemias, with regard to specific antigenicity. Leukaemias which had arisen spontaneously in 6-8 months old AKR mice were accordingly investigated for the possible presence of tumour antigen(s). Preliminary attempts to obtain cytotoxic sera from AKR mice inoculated with low doses of AKR lymphoma tissue were not rewarding. Therefore, Passage A tumours induced in C3H/BI or C57BR mice were used for pretreatment.

Groups of 2-month-old AKR or C3H mice were inoculated with cells from Gross tumours with a previously known tumour antigenicity (GHA, GBA, GBE) and according to procedures previously published<sup>1,2</sup>. Serum from these animals was then tested for cytotoxic activity against six different AKR leukaemias, primary or iso-transplanted (Table 1). The mean values given in the tables are obtained from several experiments with different serum pools. The figures given in parenthesis show the range of variation between these different serum pools. Of the six AKR tumours tested, three were found to be sensitive to cytotoxic action in the great majority of experiments (26 out of 39), while one of the other three was sensitive in only one case (out of 15). Lymph-node tissue from apparently normal 2-month-old AKR mice and 4-6-month-old mice in the preleukaemic stage did not reveal any cytotoxic sensitivity (0 out of 30). A cytotoxic effect of these sera was registered on Passage A-induced tumour cells as previously demonstrated<sup>2</sup>. Normal lymph-node cells from syngeneic donors were not affected; some of the data are not included in Table 1.

Table 1. CYTOTOXIC EFFECT\* ON SPONTANEOUS (*AKR*) AND GROSS VIRUS-INDUCED LEUKAEMIAS  
Cytotoxic index, mean and range

Serum donor	Passage A tumour inoculation	<i>AKR</i> preleukaemic lymph-node cells		<i>AKR</i> leukaemias		Syngeneic Passage A leukaemias
		2 months	6 months	Sensitive	Non-sensitive	
<i>AKR</i>	<i>GHA</i>	0.12	0.02 (0-0.08)	0.36 (0.16-0.68)	0.06 (0-0.11)	—
<i>AKR</i>	<i>GBB</i>	0.01 (0-0.3)	0 (0)	0.34 (0.16-0.69)	—	—
<i>C3H</i>	<i>GHA</i>	0 (0)	0.04 (0-0.17)	0.26 (0.16-0.41)	0.04 (0-0.16)	0.37 (0.18-0.74)
<i>C3H</i>	<i>GBA</i>	—	0.01 (0-0.04)	0.34 (0.16-0.51)	0.11 (0.08-0.14)	0.32 (0.27-0.42)

\* Cytotoxic index was defined as: percentage of living cells in control minus percentage of living cells in test, all divided by the former figure. A cytotoxic index exceeding 0.15 was considered to signify a positive effect<sup>2</sup>.

In *C57BR* mice, immunization was also performed with two of the sensitive *AKR* leukaemias, A2 and A6. Although only sera without a cytotoxic effect on *AKR* lymphocytes were used, a reaction was found against both *AKR* leukaemias and syngeneic Passage A tumours (Table 2).

Some of the spontaneous *AKR* leukaemias thus seem to possess the same tumour antigen as that found in the leukaemias induced by Passage A virus. In other *AKR* leukaemias, which were morphologically identical, this antigen could not be detected by the direct cytotoxic test.

The fact that some *AKR* leukaemias were sensitive to a cytotoxic serum, while others were not, may reflect a quantitative difference in the number of antigenic receptors on the tumour cells. Absorption experiments indicated that this, rather than a qualitative difference, was probably the case. Crude suspensions of both sensitive and non-sensitive *AKR* lymphoma cells were effective in absorbing cytotoxic sera, while lymph node cells from apparently healthy *AKR* mice, 2 or 6 months old, were ineffective. Quantitative work is now in progress, since the absorption capacity should compare with the sensitivity<sup>5</sup>.

It is, however, not possible to rule out the possibility that the virus is the stimulating antigen and that the sensitivity to cytotoxic action is due to a difference in the amount of virus produced per tumour cell. A third possibility is that a qualitative difference exists between the spontaneous leukaemias<sup>6</sup>. The Passage A virus strain may represent a selection and concentration of one of several agents responsible for leukaemias in *AKR*. The experiments reported here, however, make this last hypothesis less likely. The cross-reactivity which could be demonstrated by cytotoxic tests and absorption experiments between Passage A-induced tumours and several of the tested *AKR* leukaemias indicates that the Gross virus plays the most important part in induction also of the *AKR* leukaemias. It should be mentioned that another recently discovered antigen, the *TL* antigen<sup>7</sup>, has not been found in *AKR* leukaemias or in leukaemias induced by Passage A Gross virus.

The subsequent step was to examine the properties of sera from untreated *AKR* mice. Serum was therefore taken from untreated mice of different ages and tested on Passage A leukaemias and sensitive *AKR* leukaemias. No cytotoxic effect was demonstrated in serum from 2-month-old or from leukaemic *AKR* mice. When sera from mice 4-6 months old were tested, a weak and varying cytotoxic effect (C.I. = 0.13-0.31) was found. A similar increasing cytotoxic activity in sera from preleukaemic mice has been found in *C3H* mice injected with Passage A virus when newly born<sup>8</sup>. The serum titre was generally low during the first months after virus inoculation. After several months mice with negative and positive sera were found (C.I. = 0.12-0.56) before macroscopical tumours had developed.

The absence of detectable serum antibodies in 2-month-old *AKR* mice confirms the results of Axelrad<sup>9</sup>. He found no resistance to colony formation by lymphoma cells in young adult *AKR* or *C3H* mice inoculated with Gross virus when newly born. Instead there was an increase of tumour cell proliferation, which was interpreted as a

state of tolerance in the animals exposed to or carrying leukaemogenic virus at birth.

It is not yet clear why there should be a low production of specific antibodies in the preleukaemic mice. It is known that the presence of thymus tissue is essential to tumour genesis in this type of lymphatic leukaemia<sup>10,11</sup>. Malignant cells appear first in the thymus, from where they spread to other parts of the lymphatic system, giving rise to a generalization of the disease. As long as lymphoma cells stay in the thymus, they should be protected from the humoral antibodies by the immunological barrier of the thymus.

Table 2. CYTOTOXIC EFFECT OF *C57BR* SERA ON SPONTANEOUS AND GROSS VIRUS-INDUCED LEUKAEMIAS

Tumour inoculation	<i>AKR</i> preleukaemic lymph-node cells		<i>AKR</i> sensitive leukaemias	Syngeneic passage A leukaemias
	2 months	6 months		
<i>GHA</i>	0.06 (0.05-0.07)	0.05 (0-0.13)	0.27 (0.16-0.42)	0.40 (0.28-0.52)
<i>GBB</i>	0 (0)	—	0.22 (0.05-0.40)	0.31
A2, A6	0 (0)	—	0.39 (0.38-0.41)	0.37 (0.17-0.42)

It is possible that the first tumour cells that spread from the thymus stimulate the production of specific antibodies in the host. A parallel may be drawn with the stimulation that occurs when low doses of syngeneic Passage A tumour cells give rise to a specific resistance to transplantation and to cytotoxic antibodies<sup>1,2</sup>. The relatively small amounts of antibodies found in preleukaemic *AKR* mice are probably insufficient to prevent outgrowth if a large number of tumour cells erupt from the thymus. The same destruction of transplantation resistance is found when a large number of Passage A lymphoma cells is administered to animals immunized with Passage A-induced tumour cells.

The results reported here are indicative of serologically detectable properties, common for some of the spontaneously occurring *AKR* leukaemias and the Gross virus Passage A-induced leukaemias.

## RADIOBIOLOGY

### Evidence for the Existence of Non-exchangeable Calcium in Human Urine

It is customary to interpret the results of kinetic metabolic studies with radioactive tracers in terms of compartmental models. In the case of calcium, it is usual to assume the existence of a central pool of exchangeable calcium the specific activity of which is equal to that of

the plasma. Several workers have found discrepancies between specific activities of plasma and urine samples in various species<sup>1-5</sup> though others have not<sup>6,7</sup>. As far back as 1930 Brull<sup>8</sup> suggested that "what is excreted and concentrated by the kidney is the very part of the calcium which is diffusible but inactive and useless". If this were the case, it would seem likely that any differences between urinary and plasma calcium specific activities might be attributable to the presence of calcium in the central pool in chemical forms which do not exchange, or exchange only slowly, with ionized calcium. Recently, Giese and Comar<sup>5</sup> have demonstrated that there is, in fact, a non-exchangeable calcium fraction in sheep plasma. In the present work, it is shown that a similar non-exchangeable fraction occurs in normal human urine and presumably in the plasma.

The urine samples studied were either freshly collected specimens from normal persons or were taken from 24-h pooled collections from patients; the latter specimens were stored at 4° C with toluene as a preservative. The pH of the urine was not altered. About 0.1 µc. of calcium-47 solution in the form of chloride (Radiochemical Centre, Amersham) was added to 50–70 ml. of urine which was then incubated in a closed container for approximately 24 h at 37° C. After incubation, a portion of the urine was passed through a cation exchange resin ('Zeokarb 225' in the sodium cycle); using a column 7-mm diameter and 10-cm long. Chemical calcium in the treated and untreated urine was estimated by titration with EDTA using murexide as indicator and also by absorption flame photometry as described by Baker<sup>9</sup>; good agreement between the two methods was obtained. Specimens, the chemical concentration of calcium of which was too low for accurate measurement, were concentrated by evaporating to dryness in a platinum dish, ashing over a bunsen burner flame and reconstituting to a smaller volume in N/10 HCl. The calcium-47 content of each treated urine was compared with that of the corresponding untreated specimen in a well-type scintillation counter with the discriminator level set to eliminate scandium-47. Usually only a small fraction of the calcium-47 passed through the resin unabsorbed, but a greater proportion of the chemical calcium was recovered. It is convenient to define the effective non-exchangeable calcium ( $C_{NE}$ ) as that amount of unlabelled calcium which would have to be present in the processed urine to account for any difference in its specific activity compared with that of the original specimen; though this almost certainly represents an oversimplification. This is calculated using the expression:

$$C_{NE} = C_2 - A_2(C_1 - C_2)/(A_1 - A_2) \text{ mg per cent}$$

where  $A_1$  and  $A_2$  are the original and final count rates (c.p.m.), and  $C_1$  and  $C_2$  the initial and final concentrations of chemical calcium (mg per cent).

It can be seen from the results in Table 1 that the urines examined contained variable amounts of effectively

non-exchangeable calcium, in two cases exceeding 40 per cent. It is evident that this fraction is firmly bound since it is not removed by a strongly acidic unfunctional resin; increasing the incubation period to 48 h has little effect, and in several experiments increasing the pH to 10 or more also had little effect. Further investigations are in progress on the chemical nature of the non-exchangeable calcium, but it is already clear that this fraction is only a part of the complexed calcium fraction since calcium as citrate is readily extracted by the resin used. The demonstration of non-exchangeable calcium in plasma is necessarily difficult, since its preferential excretion would result in it being only a small part of the central pool, though it would have a very large turnover rate. Giese and Comar found it necessary to use starved sheep in order to show the existence of such a pool in plasma; and it is noteworthy that the highest non-exchangeable fraction in the present series was found in a patient with malabsorption syndrome who had hypocalcaemia as well as hypocalcaemia. Conversely it was not possible to derive a figure for the non-exchangeable calcium in urines with a high calcium content; the negative values shown in Table 1 for such urines may be due to experimental errors.

It has been pointed out by Veall and Parsons<sup>10</sup> that the use of a model which does not distinguish between ionized and complexed calcium for the interpretation of radio-calcium tracer data is likely to lead to questionable conclusions, at least so far as the quantitative aspects are concerned. Furthermore, the existence of an appreciable non-exchangeable calcium fraction in urine may account for some of the difficulties which have been encountered by many workers in determining accurately the chemical calcium content of urine samples<sup>11</sup>.

The cost of the calcium-47 used in this work was covered by research contract No. 80/RB between the International Atomic Energy Agency and the Department of Medicine, Guy's Hospital Medical School.

## BIOLOGY

### *Mansonia crassipes* as the Natural Vector of Filarioids, *Plasmodium gallinaceum* and Other Plasmodia of Fowls in Ceylon

NILES<sup>1,2</sup> recently reported an infective larva of a filarioid and an unidentified *Plasmodium* from *Mansonia crassipes* in Ceylon. Since then a number of *M. crassipes* from the same locality (Hokkandara, in the suburbs of Colombo) were found infected, the mosquitoes frequently having both oocysts and sporozoites as well as filarial infections. Two types of oocysts and two types of infective filarial larvae were seen.

As *M. crassipes* was found to be ornithophilic, the parasites were considered to be of avian origin. In view

Table 1

Para- site(s)	<i>Plasmodium</i> , microfilariae and trypanosome	<i>Plasmodium</i> and micro- filariae	<i>Plas- modium</i> only	Micro- filariae only	Trypano- some only	Nega- tive
No. of fowls	1	5	4	1	1	6

of this, blood films of country fowls from the locality were examined. Eighteen fowls have been investigated since August 1964 and the results are summarized in Table 1.

These results strongly suggested that the fowl is the vertebrate host of the parasites in *M. crassipes*. Accordingly, the following preliminary experiments were carried out: (a) Sporozoites from wild-caught *M. crassipes* were inoculated subcutaneously into day-old chicks. (b) Infective filarial larvae from wild-caught *M. crassipes* were inoculated subcutaneously into day-old chicks. (c) Blood from *Plasmodium*- and trypanosome-infected fowls was inoculated intraperitoneally into day-old chicks.

The results obtained were as follows:

(a) Sporozoite-inoculated chicks became infected with three different species of *Plasmodium*. The incubation period for two of these was about 15 days. One of the latter was indistinguishable from *P. gallinaceum*, while the other produced mostly elongate gametocytes which tended to grow round the host cell nucleus rather than to displace it. This appeared to be a new parasite. Prof. P. C. C. Garnham and Prof. A. Coradetti, who examined the parasites, were of the same opinion. The third species appeared after an incubation period of 30 days and the parasite was very much like *P. lophurae* with the characteristic vacuolation of the cytoplasm. Of all three species this was the least pathogenic to the chickens, which lost the infection in seven days.

(b) Infective filarial larvae with three caudal papillae and approximately 1,800 $\mu$  in length (described by Niles<sup>1</sup> as being closely similar to those of *Wuchereria bancrofti*) were inoculated into two day-old chicks, one receiving 38 and the other 14 larvae. The first chick became microfilaria-positive after 29 days and the second after 25 days. The microfilariae were 280–300 $\mu$  in length and appeared to be similar to those of *W. bancrofti*, but lacked a sheath. The development in the mosquito took place in the thoracic muscles. The first chick was killed 24 days after it began to show microfilariae, and 6 adult female and 12 adult male worms were recovered from its peritoneal cavity. These and the other adult filarioids from fowls are now being examined.

The second type of filarial larva found in *M. crassipes* developed in the fat body. The mature larva was short (920–1,020 $\mu$ ) and devoid of any distinct caudal papillae. Fourteen infective larvae of this type were inoculated into a day-old chick which died 24 days later without showing microfilariae. No adult worms were recovered from it.

(c) Blood from five of the *Plasmodium*-infected fowls was inoculated intraperitoneally into day-old chicks. The incubation period was 8–10 days, and the parasites were mostly of the *P. gallinaceum* type. The various strains isolated showed different degrees of virulence to the chickens. The trypanosomes did not show up in the chickens after blood inoculation.

It would appear from these observations that *M. crassipes* is the natural vector of *P. gallinaceum* of fowls in Ceylon and possibly of other species of *Plasmodium* of fowls or of related avian hosts. If one of the other plasmodia from *M. crassipes* is in fact *P. lophurae* then this will be the first record of *P. lophurae* from this part of the world. We are, however, not certain whether the fowl is the natural vertebrate host of *P. lophurae* in Ceylon.

We have seen crithidial forms in the midgut of engorged wild-caught *M. crassipes*. This mosquito may, therefore, prove to be the vector of the trypanosome as well. The

trypanosome differs from *Trypanosoma gallinarum* and *T. calmettei* which have previously been reported from fowls.

So far five different types of microfilariae have been found by us in fowls. One of these is similar to that obtained in the chick experimentally infected with infective larvae from wild-caught *M. crassipes*. Perhaps the most interesting feature here is that the pre-patent period of at least one of the filarioids of this easily available laboratory animal is only 25–30 days. This parasite will therefore prove most valuable in teaching and research.

Because the infective larva of one of the filarioids resembled that of *W. bancrofti* we tested the susceptibility of laboratory-bred *Culex pipiens fatigans* to infection with four of the five types of microfilariae seen in fowls. This mosquito fed avidly on the fowls but was not receptive to any of the microfilariae.

### Age Determination in Baleen Whales (Mystacoceti)

THE determination of the age of cetaceans is of importance for the organization of a rational exploitation of their stock. Age determination of baleen whales by the layers of ear plugs<sup>1,2</sup> does not always give accurate results and raises several technical difficulties<sup>3</sup>.

When staining the transverse section of baleen plate with haematoxylin and eosin, multiple layers in the walls of large and small tubules composing the medullar layer of plates are clearly seen. An investigation of the structure of baleen plates of two finwhales (*Balaenoptera physalus*), the age of which was determined with the accuracy of  $\pm 0.5$  years by means of the analysis of ear plug layers, showed a certain correlation to exist between the maximal number of layers in small tubules and the age of the animal (Fig. 1a). An examination of a large number of such tubules revealed that in some of them (about 10 per cent of the total number) no layers could be seen at all, the wall of the tubules being smoothly or spottily stained. A less clear manifestation of stratification was found in large tubules of the baleen plate.

In the tubules of the baleen plate of a considerably older animal the number of layers is much greater than that in three to four year old ones (Fig. 1d).

The character of the stratification is not related to the location of the section either at the base, in the middle or in the upper part of the baleen plate. There are specimens which show the stratification of large external tubules to be more pronounced at the apex of the baleen plate.

We have examined the histological structure of the baleen plates in several *Mystacoceti* species caught by coastal whale trading stations on the Kuril Islands and by the inhabitants of the Chukotsk Peninsula. In sections of *Balaenoptera musculus*, *B. borealis*, *B. acutorostrata*, *Megaptera nodosa*, and *Balaena glacialis* the layers of tubules in the medullar layer of the baleen plate were clearly seen.

The material at our disposal has been insufficient for firm conclusions to be drawn concerning the relation of tubule stratification of the baleen plate to the age of

Fig. 1. Transverse sections through a small tubule of the fin-whale (*Balaenoptera physalus*) baleen plate (haematoxylin and eosin), a, age of the animal  $3 \pm 0.5$  years; b, age  $4 \pm 0.5$  years; c, an older animal ( $\times c. 75$ )

Fig. 2. Transverse section through a small tube of the baleen plate of a seiwhale (*B. borealis*) of an unknown age

the animal. However, the results obtained show that there is a possibility that such a relation exists. By examination of further specimens it may be possible to develop a new and simpler method for the determination of the age of baleen whales.

### A Triennial Copepod (Crustacea) in the Temperate Zone

BOTH marine and freshwater copepods have, with one exception from the high arctic<sup>1</sup>, generally been regarded as having a life-cycle of one year or less. A study of the freshwater planktonic copepod *Cyclops scutifer* Sars now in progress in Scandinavia and in North America has shown, however, that this species has a 3-year cycle in a small lake near Oslo, Norway.

The lake, Store Tryvann, is situated at 60° N and at an elevation of 395 m above sea-level, has an area of 0.0437 km<sup>2</sup>, and a maximum depth of 16 m, is mesohumic, and surrounded by dense coniferous forests. The surface temperatures rise to about 20° C in the summer, and bottom temperatures go only slightly below 4° C. The mean air temperature of the surroundings (1931–60) for July is 14.3° C.

The seasonal cycle of *C. scutifer* is rather complex, its main outlines being as follows: the period of reproduction occurs in the summer, and nauplii (Fig. 1, 0) develop to the penultimate naupliar stage during the autumn and remain at this stage throughout the winter. During the following spring the nauplii develop to small copepodids (Fig. 1, 1) most of which, in the course of the summer, go

into diapause<sup>2,3</sup> as copepodids II and III in the bottom mud, where they stay in a dormant condition until the next spring. During the spring of the second year the small copepodids develop into large copepodids of stages IV and V, and most of them descend to the bottom mud for a second period of diapause (Fig. 1, 2). After having spent the autumn and winter in diapause these large copepodids develop into reproducing adults in the course of the spring and early summer of the third year. The adults die off during the summer. There is, however, some evidence that a fraction of the population of large copepodids may develop into adults in the second summer without a second diapause, thus producing a secondary maximum of adults and a new wave of reproduction later in the same summer. The maximum of adults in Fig. 1 (3) is therefore probably composed of some 2-year and some 3-year-old individuals. It is of course also possible that a few individuals survive more than 3 years.

Fig. 1. Relative distribution of the population of *Cyclops scutifer* in Lake Store Tryvann on July 25, 1962. Cross-hatched bars, in the plankton; black bars, in diapause in the bottom deposits. Figures indicate the different year classes referred to in the text

The 'dualism' previously observed in Scandinavian populations of *C. scutifer*<sup>4-6</sup> can now most simply be explained by the existence of different year classes in the population.

The prolongation of the seasonal cycle in this species may be considered as an adaptation to arctic conditions which is maintained also in the temperate zone.

### A Model of Tumour Growth in Irradiated Hosts

It has been found that local irradiation of the transplantation site prior to grafting experimental animal tumours influences the subsequent growth rate of the tumours and the survival time of the tumour-bearing hosts<sup>1,2</sup>. While the results of the experiments indicated that irradiation of the host tissue slowed the growth of the tumours, more precise interpretation of the data seemed desirable. The following simple model was thus developed. In the light of this model, experimental data can be interpreted in a more meaningful fashion. In addition, the approach utilized in the model may be useful in other problems of host-tumour interaction.

Assume that a tumour consisting of  $n$  cells will double as soon as it has been exposed to a given quantity per cell ( $m$ ) of some limiting metabolite. If  $A$  is the effective area of the capillary bed and  $J$  is the transcapillary flux of this limiting metabolite, then the doubling time,  $t_d$ , is given by:

$$t_d = \frac{mn}{AJ} \quad (1)$$

Now irradiation of the host changes  $A$  by  $\Delta A$  and  $J$  by  $\Delta J$ . Call these new values  $A'$  and  $J'$ . The doubling time of the tumour in an irradiated host,  $t_d'$ , is  $mn/A'J'$  and:

$$\frac{t_d}{t_d'} = \frac{A'J'}{AJ} = 1 - \frac{\Delta A}{A} - \frac{\Delta J}{J} + \frac{\Delta A \Delta J}{AJ}$$

The magnitudes of  $\Delta A/A$  and  $\Delta J/J$  are likely to be rather small,  $\Delta A \Delta J/AJ$  is much smaller, so as an approximation:

$$\frac{t_d}{t_d'} = 1 - \frac{\Delta A}{A} - \frac{\Delta J}{J} \quad (2)$$

Since  $\Delta A/A$  and  $\Delta J/J$  are properties of the host animal, they may change as the host tissue recovers from the effects of irradiation, and hence are functions of time. For a slowly growing tumour the repair per generation of tumour cell will be greater than for a rapidly growing tumour, so as approximations:

$$\frac{\Delta A}{A} = R + Kt_d \text{ and } \frac{\Delta J}{J} = M + Nt_d \text{ (K and N negative)}$$

On substitution into equation (2):

$$\frac{t_d}{t_d'} = F + Gt_d, \text{ where } F = 1 - R - M, \text{ and } G = -K - N \quad (3)$$

Fig. 1. Growth rate depression induced by irradiation (3,000 r.) of the tumour bed plotted against the growth rate of the same tumour in an unirradiated bed. Standard error of estimate is indicated. Data are from ref. 1 (stars) and ref. 2 (dots).

Expressed in terms of the growth rate,  $B$  ( $B = (\log 2)/t_d$ ):

$$\Delta B = PB - Q, \text{ where } B - B' = \Delta B, P = 1 - F, Q = G \log 2 \quad (4)$$

This equation predicts the expected relationship between the growth rate ( $B$ ) of the control tumour and the growth rate depression ( $\Delta B$ ) induced by prior irradiation of the host. As can be seen in Fig. 1, the experimental data verify this prediction ( $P = 0.72$  and  $Q = 0.013$ ).

The magnitude of the effect of pre-transplantation irradiation of the tumour bed appears to be related to the normal growth rate of the tumour. The relationship that exists can be predicted by assuming quantitative alterations in the effective capillary bed and in the transcapillary flux. The nature and relative importances of these changes are not immediately apparent; experimental work based on this model is in progress.

I thank Prof. Kelly H. Clifton for his advice.

### In vitro Conversion of Neutral Gibberellin-like Substances from Potato Tubers

RECENTLY, a chemically neutral substance, separated chromatographically from a methanol extract of potato tubers, was reported to stimulate elongation of 'Morse's Progress' dwarf pea plants grown under red light<sup>1,2</sup>. This bioassay is particularly sensitive to certain gibberellins, and the neutral substance, tentatively termed potato factor I, was therefore considered gibberellin-like. The substance was separated under well-controlled conditions to avoid the possibility of contamination by acid substances. Its discovery was of considerable interest since gibberellin-like substances that exhibit activity on the dwarf pea bioassay were previously found only in the acid fraction of plant extracts. The growth promotion by potato factor I became of even greater interest when, after two weeks standing and rechromatography, its activity had disappeared from its original place on the chromatogram and a new zone, now giving an acid test and showing much higher biological activity, appeared at  $R_F$  0.5-0.6.

To prepare the neutral fraction, 1 kg of peelings and buds from well-sprouted 'Red Pontiac' potato (*Solanum tuberosum* L.) tubers was extracted twice with methyl alcohol at 0°C. The alcoholic extracts were evaporated to the water phase which was extracted with ethyl acetate at pH 7.5. Basic substances were removed by shaking the ethyl acetate phase with 1 per cent sulphuric acid, leaving only neutral substances. The neutral fraction was concentrated and streaked on Whatman No. 3 MM paper and developed in isopropyl alcohol/ammonium hydroxide/

Table 1. The response of 'Morse's Progress' dwarf pea plants to eluates of the original neutral fraction and to the rechromatographed  $R_F$  0.3-0.4 eluate after standing two weeks at room temperature

Fraction	$R_F$	Dwarf maize $d_1$	Dwarf pea $d_1$
		Per cent of control	
Original	0.3-0.4	100.2	122.1
Neutral	0.4-0.5	84.9	112.7
	0.5-0.6	82.9	115.8
Rechromatographed	0.3-0.4	89.7	107.2
	0.4-0.5	89.7	143.2
$R_F$ 0.3-0.4	0.5-0.6	109.3	256.2

Fig. 1. The response of dwarf pea plants to the original neutral fraction from potato peelings and buds. Shaded area is potato factor I. Developed in isopropyl alcohol : ammonium hydroxide : water (10 : 1 : 1 v/v). Note the absence of colour development when chromatogram strips were sprayed with bromocresol green (BCG)

water (10 : 1 : 1 v/v). In separate tests, methyl alcohol extraction in the presence of nitrogen gas increased the yield of the neutral substance.

Potato factor I showed activity only on dwarf pea plants and affected neither dwarf maize  $d_1$  nor  $d_8$  (Table 1). The  $R_F$  0.3–0.4 eluate was dried and left standing for two weeks under aerobic conditions at room temperature. It was then dissolved in methyl alcohol and again chromatographed as described previously. Surprisingly, the  $R_F$  0.3–0.4 activity had disappeared completely and a new promoting zone had appeared at  $R_F$  0.5–0.6. This zone now gave an acid test with bromocresol green (BCG) (Fig. 2). Moreover, the activity of the new zone on dwarf pea plants was doubled; it also showed slight activity on dwarf maize  $d_8$ . Thus it appears that a substance(s) of the  $R_F$  0.3–0.4 eluate, chemically neutral and of relatively low activity, may have changed to a substance(s) that migrates to a higher  $R_F$ , is acid in nature, and shows qualitatively and quantitatively different biological effects. This kind of change was also noted in a 50 per cent alcoholic polyoxyethylene sorbitan monolaurate ("Tween-20") solution

Fig. 2. The response of dwarf pea plants to the rechromatographed  $R_F$  0.3–0.4 eluate from the neutral fraction of potato peelings and buds. Note the appearance of colour after a chromatogram strip was sprayed with bromocresol green (BCG)

of the extract which was kept at 5° C for four weeks and which also increased dramatically in biological activity.

In an attempt to learn something of the chemical nature of the new zone it was separated using thin layer chromatography with silica gel-G ('Kieselguhr G') as stationary phase and benzene/propionic acid/water 8:3:5 (v/v) as developing solvent. The plate was sprayed with 5 per cent sulphuric acid in 98 per cent alcohol and a blue-green fluorescent spot was detected at  $R_F$  0.52 in ultra-violet light. This  $R_F$  corresponds to that of gibberellin  $A_1$ . Of course, additional information must be obtained before identification of the new form is assured. Lack of pure crystalline potato factor I prevented a direct attack on the mechanism of the reaction and the *in vitro* nature of the experiments permits only the most cautious speculation.

This may serve to highlight the significant aspects of this report.

The low activity of potato factor I and the much higher activity of the new active acid region suggest that potato factor I is a comparatively inactive, conceivably bound or precursor form of gibberellin. This speculation is supported by the very high activity of the 0.5–0.6 zone on dwarf peas and the new, although slight, activity on dwarf maize  $d_8$ .

The manner in which the apparent change occurred and the higher yields of 0.3–0.4 under anaerobic extraction conditions indicate a very simple, possibly oxidative, reaction. The response of dwarf pea, but not of dwarf maize, to potato factor I is of interest since the former might have the ability to convert the neutral to the acid form of the compound. The possibility of related changes occurring *in vivo* is suggested in the experiments of Hashimoto and Rappaport<sup>3</sup> in which incubation of bean seeds with gibberellin  $A_1$  resulted in a definite increase in activity of the neutral fraction.

Additional evidence for bound forms of gibberellins is presented by McComb<sup>4</sup> in which a homogenate of runner bean seeds yielded several times the original gibberellin-like activity after treatment with ficin, a proteolytic enzyme. Moreover, Murakami<sup>5</sup> reported the formation of a gibberellin  $A_1$  glycoside after incubation of cucumber leaf disks in the growth substance. The glycoside could be hydrolysed into gibberellin and sugar moieties with either dilute hydrochloric acid or the enzyme emulsin.

A better understanding of potato factor I must await its isolation, crystallization and use in physiological experiments.

This work was supported by U.S. Public Health Service grant EF-61. We thank Dr. B. O. Phinney for supplying seeds of dwarf maize.

### Embryo Sac Development in *Moquiniella*

THE Loranaceae are characterized by extremely long embryo sacs the tips of which reach up to various lengths in the style<sup>1</sup>. In four genera—*Barathranthus*<sup>2</sup>, *Helicanthera*<sup>3</sup>, *Tapinostemma*<sup>4</sup> and *Tupeia*<sup>5</sup>—they invade the stigma ascending as far as its apex. While working on *Moquiniella rubra* (Spreng. f.) Balle, a species endemic to South Africa, we observed that the tip of the embryo sac not only ascends

Figs. 1-4. Fig. 1. Tip of organized embryo sac ( $\times c. 360$ ). Fig. 2. Longitudinal section of stigma showing the curved position of an embryo sac ( $\times c. 40$ ). Fig. 3. Longitudinal section of gynoecium with six embryo sacs of which three (1, 2 and 3) have curved tips (diagrammatic) ( $\times c. 2-4$ ). Fig. 4. Magnified view of the stigmatic region from Fig. 3 showing four embryo sacs, three with curved tips ( $\times c. 40$ ). *br*, bract; *ca*, calyculus; *hyp*, hypostase; *pem*, pro-embryo; *sn*, secondary nucleus; *syn*, synergid; *z*, zygote

up to the apex of the stigma but also elongates further and curves downward.

*Moquiniella* is a stem parasite which grows on various species of *Acacia* and *Rhus*. It is a glabrous shrub with opposite leaves and brown flowers borne in umbellets. The flowers are 42-44 mm long, sub-sessile, pentamerous, hermaphrodite, and subtended by a small bract. The calyculus forms a 5-lobed rim and is devoid of any vascular supply. The corolla lobes are initially straight but become strongly reflexed at anthesis; the stamens are epipetalous and basifixed; and the fruit is an ellipsoidal pseudoberry.

The stylar canal is continuous with the central ovarian cavity and a plate of 5-8 hypodermal archesporial cells differentiates at its base. These cells elongate considerably and divide mitotically, forming a large mass of sporogenous cells which function directly as megaspore mother cells. After meiosis linear tetrads are formed, and the development of the embryo sac conforms to the Polygonum type. During megasporogenesis, several mother cells, dyads and tetrads degenerate so that only a few gametophytes develop. Two and 4-nucleate stages are gone through as usual, and at the 4-nucleate stage the tips of embryo sacs elongate into the style. Owing to their unusual length the gametophytes could not be dissected out in entirety, and it could not be established if a 6-nucleate stage (formed due to an earlier division of the two lower nuclei of 4-nucleate embryo sac) precedes the 8-nucleate condition<sup>1</sup>. The basal end of the embryo sac (situated in the ovary) forms a caecum leaving the antipodal cells *in situ*. The lower polar nucleus migrates into the upper part of the embryo sac, fuses with the upper polar nucleus, and the secondary nucleus becomes closely appressed to the egg (Fig. 1).

Four to nine embryo sacs extend into the style and stigma (Fig. 3). A very unusual feature, hitherto unreported, is the bending downward of the tips of some of the embryo sacs for 2-4 mm (Figs. 2-4). Therefore, the final shape of the curved embryo sac resembles an inverted J.

The maximum length of the straight arm of the embryo sac is 44 mm and of the curved portion 4 mm. To the best of our knowledge *Moquiniella* shows the longest embryo sac in angiosperms with a close approach to another loranthaceous genus, *Tapinostemma*<sup>2</sup>, which has a gametophyte 42 mm long.

The inverted tips of some of the embryo sacs in a style showed an egg apparatus while others had pro-embryos (Fig. 4), which indicates that fertilization occurs in this position. Whether such embryos reach maturity could not be ascertained as we had very little material of the developing fruits.

We thank Prof. P. Maheshwari for his advice, Prof. E. S. Twyman, Rhodes University, Grahamstown, South Africa, for providing the material; and the Ministry of Education, Government of India, for the award of a research training scholarship to one of us (B. R.).

## ENTOMOLOGY

### Effect of Hormones on the Respiration of Body Fragments of Adult *Pyrrhocoris apterus* L. (Hemiptera)

PREVIOUS investigations of normal adult female *Pyrrhocoris* have demonstrated cyclic changes in the rate of oxygen consumption closely correlated with cycles of ovarian development and oviposition. These cycles disappear in females deprived of corpus allatum; when the corpora cardiaca were also removed, the absolute level of oxygen consumption decreased to low and steady levels similar to those encountered in normal adult males or diapausing adult females. The hormones seem to affect the total metabolism indirectly. For example, the activation hormone (AH) secreted by the brain neurosecretory cells—corpora cardiaca system—is a trophic factor which stimulates metabolic activity in tissues engaged in digestion and food utilization. The corpus allatum hormone (CAH) is thought to regulate metabolic activity in reproductive system<sup>1-3</sup>.

The high respiratory metabolism of normal adult females was shown to be composed of three main components; namely: (1) the reproduction metabolism, dependent on the CAH; (2) the digestive metabolism, dependent on the AH but independent of the CAH; (3) muscle metabolism and the basal cellular metabolism, identical with diapause metabolism, which are essentially independent of both hormones. The first of these metabolic components is absent in adult females deprived of their corpora allata. The first and the second are lacking in females deprived of both the CAH and the AH. As in normal males the total body respiration is then dependent solely on the third component<sup>1</sup>.

In the work recorded here these suggestions have been subjected to a further experimental analysis, using body fragments. As is well known, the tracheal system of insects ensures the oxygen supply to each tissue or cell independently of the circulatory system<sup>4,5</sup>. The isolated body fragments with uninjured tracheation retain their metabolic activity for a long time, until the reserve substrate material is completely exhausted. Thus, for example, it is not uncommon for an isolated pupal abdo-

Fig. 1. Oxygen consumption of the whole-body (whole columns), thoracic fragments (black areas) and abdominal fragments (stippled areas) in 15 days old *Pyrrhocoris* adults. A, normal active females; B, females deprived of the corpus allatum soon after adult emergence; C, females with diapause induced by short photoperiod; D, normal males

men to develop and even to reach the adult form if the necessary hormones are supplied<sup>4</sup>. In our laboratory we have succeeded in keeping alive the abdomens isolated from the sawfly prepupae for more than three years.

Oxygen consumption was determined by the Warburg technique. The experiments were initiated by measuring oxygen consumption of the individual intact specimens. The specimens were then removed from the manometers and asphyxiated by submerging them under water for 15–20 min. Each individual was then decapitated and dissected in two separate fragments. The thoracic fragment contained the three thoracic segments with the legs and the complete thoracic somatic musculature; the thoracic part of the intestine, the fat body, and the salivary glands were taken out. The abdominal fragment contained the whole reproductive system, most of the intestine, and a great part of the fat body, etc. The separate fragments were quickly transferred into the respiratory vessels and the oxygen consumption was determined four times at 30-min intervals. The oxygen consumption of the fragments was found to be constant for 5–10 h.

The experiments were performed on the following groups of 15–30 specimens of 15-day-old *Pyrrhocoris* adults: (a) the normal active females at the middle of the reproduction cycle, with maximal respiration rate, with intestine full of food and with ripening eggs in the ovaries; (b) females deprived of their corpus allatum, with intermediate respiration rate and suppressed ovarian development; (c) diapausing females (obtained by rearing under conditions of 8 h photoperiodic illumination) with low respiratory rate, suppressed hormonal activity, arrested ovarian development and reduced digestion; (d) normal males with low respiratory rate, reduced digestion, etc.<sup>2</sup>. The weight of the thoracic fragments was about 22–24 mg in all groups. That of the abdominal fragments was about 48–52 mg in groups (a) and (b), and about 25 mg in groups (c) and (d) respectively.

The results are summarized in Fig. 1. They show that the thoracic fragments (containing most of the somatic muscles present in the body) maintain a similar rate of oxygen consumption in all these adults. This confirms the earlier suggestions<sup>1</sup> that metabolism of these somatic muscles is independent of hormonal activity.

A different situation occurs in the respiration of isolated abdominal fragments (Fig. 1). These fragments have a very low respiratory rate in diapausing females, where the organs of digestion and reproduction are functionally inactive. The same is true of the abdominal fragments of the normal males. The fragments isolated from the allatectomized females have a relatively higher respiration

rate, which seems to be connected with the functional activity of the digestive tube. The abdominal fragments isolated from the normal active females have the most intensive respiration rate. This can probably be explained by an enormously increased metabolic activity in connexion with the intensive digestion and egg maturation processes occurring in these insects<sup>7</sup>. Moreover, it is evident that the single abdominal fragment taken from an active female utilizes nearly twice as much oxygen as does the whole body of a diapausing female. These results indicate that the decisive part of the hormone-stimulated respiration results from increased metabolism in some tissues located in the abdomen, that is, the digestive tube, ovaries, fat body cells, etc.

These findings are consistent with the earlier suggestions<sup>1–3</sup> that insect hormones control the body metabolism indirectly by stimulating the growth processes in special target cells or tissues. The stimulated cells would themselves be responsible for the various biochemical reactions.

In the complete absence of the metamorphosis hormones the tissues that require hormonal stimulation do not grow and function. They maintain only a low, basal metabolism necessary for their preservation. This is probably the case with the abdominal tissues mentioned here. However, some of the tissues do not require hormonal stimulation. They can perform their metabolic functions in the absence of hormonal activity. As demonstrated here, these are mainly the somatic muscles of adult *Pyrrhocoris*; they have completed their differentiation during metamorphosis and their function in the adult stage is independent of growth. This suggests again that insect hormones regulate physiological processes by inducing growth in some special target cells or target tissues<sup>8,9</sup>.

### 'Gynandromorphic Effect' and the Optical Nature of Hidden Wing-pattern in *Gonepteryx rhamni* L. (Lepidoptera, Pieridae)

G. A. MAZOKHIN-PORSHNYAKOV<sup>1</sup>, examining the optical characters of insect wings in connexion with the visual perception of insects, and taking photographs using ultra-violet rays, found that the smooth, yellow surface of the *Gonepteryx rhamni* wing has a real pattern which is invisible to the human eye. He also found that such a pattern in the full sense is presented in males only. The wing of the female absorbs ultra-violet rays by the entire surface and then looks dark. Mazokhin-Porshnyakov supposed that this hidden pattern may be considered as a character of taxonomic value. This assumption has been partly supported by my work<sup>2</sup>.

It is known that wing-patterns of Lepidoptera may be conditionally divided in two groups: pigmental and optic. I say conditionally because of the absence in Nature of any pure representative of any of this group. Real patterns are usually of a combined nature. Pigmental pattern

Fig. 1

Fig. 2

Fig. 3

Fig. 4

peculiarities may be explained by the ability of a given pigment to absorb and (or) reflect the ray of a given wavelength. The optical pattern depends on effects of interference (genus *Haetera*) and diffraction (*Urania*, *Morpho*, *Apatura*, *Chlorippe*, etc.), and the visible appearance of wing-patterns of this group depends on the dip angle of light and the angle of observation. Now, naturally, the question arises: to which group does the hidden wing-pattern belong?

Once, taking photographs of *G. rhamni* in ultra-violet light and developing the film, I suddenly recognized the fact that all butterflies photographed turned out gynandromorphous: on one side the wings were like male, on the other, female. Then I remembered that the source of light (a mercury vapour lamp) had been placed so that light came from a side (the normal position was as shown in Fig. 1) and thus the observed effect may be explained only by the assumption that here we deal with the pattern of the optical group. If it were a pigmental one, the dip angle would not affect the appearance of pattern. The clear evidence of it is that in the lateral lighting the wing patterns of right and left sides are not identical ('gynandro-

morphic effect'). The hidden wing-pattern comes out exactly when the light comes toward the wing surface at an acute angle and from a distance. Figs. 1-4 depict the variation of the hidden wing-pattern depending on the position of the source of light. The arrow on each figure shows the direction of rays.

The luminescent observations of wings of these butterflies also supported the assumption concerning the optical nature of this pattern. Bright central field (for terminology see ref. 2) of the forewing luminesces in the dark-room when lighting with ultra-violet light in violet-purple colour (the range of this colour corresponds to the bright central field of the forewing in Figs. 1-4), and when a butterfly is turned, one can observe an effect much like that in *Apatura* in visible light. It is also interesting to note such an irisation in visible light in a North-American relative of *Gonepteryx*—*Zerene eurydice* Boisd.—and in some palaearctic representatives of the genus *Colias*.

Perhaps in all these cases we deal with the same effect, but in various ranges of wave-lengths. It is possible to explain this phenomenon by the presence on the *G. rhamni* wing of scales of the *Morpho* type<sup>3</sup>.

All the aforementioned may also be of importance when one seeks for a better mutual arrangement of the subject and the source of light in the photographic investigations in the ultra-violet part of the spectra.

## MICROBIOLOGY

### Isolation and Characterization of an Actinophage (Phage A) active against a Strain of *Streptomyces* producing Novobiocin

AN actinophage (phage A), active against *Streptomyces*  $C_1V_{23}$  obtained from strain S-800<sup>1,2</sup>, a producer of novobiocin, has been isolated from industrial fermentation broth cultures with scanty or abnormal mycelial growth and no antibiotic production. So far as we know, this is the first time that an actinophage destructive to a *Streptomyces* strain producing novobiocin has been isolated.

The multiplication of the phage was easily obtained by contaminating, with a single plaque or 1-2 ml. of phage suspension, a 24-30 h culture of vegetative mycelium of  $C_1V_{23}$  in  $V_{10}$  modified broth (beef extract, 5.0 g; peptone, 5.0 g; autolysed yeast, 5.0 g; pancreatic digest of casein, 3.0 g; dextrin, 25.0 g;  $K_2HPO_4$ , 1.0 g;  $MgSO_4 \cdot 7H_2O$ , 0.25 g; NaCl 0.5 g; distilled water to 1,000 ml.) and incubating on a reciprocal shaker for 24-30 h at 28° C. Under these conditions lysis of the mycelium is complete with a titre of  $10^8$ - $10^9$  phage particles per ml.

The morphological characteristics of the plaques on the  $C_1V_{23}$  strain after different periods of time at 28° C were studied, using the double-layer technique of Gratia<sup>3</sup> as follows: After 24 h, circular shaded plaques,  $\phi$  1.0-2.0 mm, with slightly clearer centre. After 48 h, circular plaques,  $\phi$  2.0-3.0 mm, with very clear centre and turbid halo at the border. After 72-96 h, circular plaques,  $\phi$  4.0-5.0 mm, very similar to the 48 h plaques (Fig. 1). After 120-144 h, the distinction between the clear centre and the turbid halo at the border tends to diminish and the plaques ( $\phi$  4.0-5.0 mm) appear more uniformly turbid. The clear part is reduced to a small central dot-like zone.

Fig. 1

Fig. 2

From the phage-lysed cultures were also isolated sensitive colonies on which the phage, instead of forming plaques, as described for the  $C_1V_{23}$  strain, formed much smaller dot-like plaques (Fig. 2) and much fewer in number:  $10^3$  on  $10^7$  phage particles employed. These results seem to indicate that, keeping the plating conditions constant, the plaque size and its morphology are characteristic of the specific host-phage system and that the host and not the phage is the more active determinant of the plaque size. They also agree with the results obtained by St. Clair and McCoy<sup>4</sup> for other actinophages and by Thiernann *et al.*<sup>5</sup> for phages active on *Streptomyces mediterranei*.

Resistant colonies were easily obtained by plating aliquots of the lysed culture broths. The criteria adopted to test the resistance of the isolated colonies were those of van Alstyne *et al.*<sup>6</sup>. In flask fermentation, the novobiocin-producing capacity of the resistant colonies was of 600–700 µg/ml. (microbial titre), practically the same as that of the sensitive parent strain.

The host-range of phage A has been determined, in a preliminary way, using the following strains of the genera *Streptomyces* and *Nocardia*: *S. griseus* 'NRRL B-150', *S. griseus* 'Waksman WC 3475', *S. lavendulae* 'ATCC 8664', *S. fradiae* 'NRRL B-1195', *S. erythraeus* 'C.B.S.', *S. viridifaciens* 'ATCC 11989', *S. antibioticus* 'Ist. Genetica, Università di Pavia—Italy', *S. diastaticus* 'ATCC 3315', *S. aureofaciens* Duggar 'NRRL 2209', *S. psammoticus* 'C.B.S. 17561', *S. hygroscopicus* 'NRRL B-1865', *S. rimosus* 'NRRL 2234', *S. niveus* 'NRRL 2466', *S. sphaeroides* 'NRRL 2449', *N. blackwellii* 'C.B.S.', *N. asteroides* 'C.B.S.', *N. erithropolis* 'C.B.S.', *N. polychromogenes* 'C.B.S.', *N. brasiliensis* 'C.B.S.', *N. tenuis* 'C.B.S.', and *N. lutea* 'C.B.S.'.

The test has been performed with the double-layer technique of Gratia and with the drops method described by Weindling *et al.*<sup>7</sup>. Under these conditions, all species and strains of *Streptomyces* and *Nocardia* tested, with the exception of *S. sphaeroides* 'NRRL 2449', have proved to be resistant to phage A. The host-range will be further investigated, using other species of *Streptomyces*, in order to define it more completely.

Phage A proved to be Ca-dependent since the addition to the broth of the Ca-sequesterant agent EDTA inhibited the lysis of the mycelium almost completely. EDTA, at concentrations inhibiting the phage lysis, was shown to be partly toxic to the mycelium while no toxic effect on the phage was observed at the same concentrations.

## Pure Culture of *Anabaena flos-aquae* A-37

SEVERAL methods have been proposed for the isolation of bacteria-free cultures of algae<sup>1-6</sup>. Methods reported to provide some measure of success, using antibiotics, ultra-violet light, chlorine compounds, etc., are fairly drastic and, in some cases, mutagenic. The problem of separating algae from bacteria may be related to a binomial distribution function in which the probability of choosing a bacteria-free algal colony in any trial varies in an unknown fashion from one trial to another. Successful, practical use of the proposed method may be expected only when the chance of choosing a bacteria-free algal colony exceeds about one in twenty.

Since the skill of the operator doubtless contributes to success, the method succeeds in proportion to the amount of operator bias employed in choosing uncontaminated colonies. This method has as its aim the separation of algae from the contaminating bacteria by the simple techniques of 'positive operator bias' coupled with numerous replication.

Accordingly, the method consists of (a) creating artificial predominance of the chosen alga by accumulation with a micropipette, (b) culture of the accumulated algal cells in liquid HGZ medium, a *tris*-buffered modification of the medium employed by Hughes, Gorham and Zehnder<sup>7</sup>, (c) culture on HGZ agar dilution plates, (d) repetition of (b) and (c) alternately to obtain uni-algal cultures and to show which is the highest dilution in which algal colonies grow well separated and in small numbers, (e) preparation of 20 replicate plates of the plate dilution which affords good colony separation, (f) daily microscopic observation of plates from which approximately 20 sub-cultures are made into liquid HGZ, (g) after incubation and growth, inoculation of 1 ml. of the HGZ liquid cultures into nutrient broth. Observation at 48 h indicates the presence or absence of bacteria.

All the algae employed have been isolated from either pond water or sewage, using micropipettes to collect several units of a species for culture. Isolates were cultured alternately in agar dilution plates and in liquid medium to produce uni-algal cultures. Cultures were incubated in the light at 40° C on HGZ. Serial dilutions of isolates in HGZ agar were observed at least once each 24 h. A low-power, wide-field microscope was employed, using magnifications of the order of 90×.

It was soon found that several replatings reduced the apparent number of types of bacterial contaminants which would grow on HGZ medium from as many as 10 to one or two types. These plating trials also indicated the limits of dilution for any given culture, beyond which growth of the alga could not be expected with useful frequency. It also suggested that, contrary to the opinions of some research workers, the bacteria often outnumber the algae by more than ten to one in what might appear to be a fairly 'clean' culture of algae grown in mineral salts medium.

Having determined the limiting dilution for the growth of a culture of algae, 20 poured plates were prepared at the limiting dilution less one. Growth was meticulously observed daily, using the wide-field microscope, to find the algal colonies growing at maximal distances from each other and from bacterial colonies. All the colonies which appeared to afford good separation from the surrounding bacteria were cut out of the agar with an inoculating needle or a micro-scalpel and placed in liquid HGZ medium for incubation. If possible, 20 cultures were made. As soon as growth was observed, sub-cultures were made in nutrient broth. Absence of growth in nutrient broth after 48 h of incubation was accepted as proof of the absence of bacteria.

When this procedure was employed, *Anabaena flos-aquae* A-37, which was isolated in this laboratory from an oxidation pond located in Mississippi, grew through the  $10^7$  dilution. Of 16 sub-cultures on liquid HGZ, 11, or almost

70 per cent, were free of bacteria as judged by sub-culture on nutrient broth. Frequent sub-culture of these bacteria-free isolates continues to prove the absence of bacteria which will grow either on HGZ medium or in nutrient broth.

While it is admittedly impossible to provide complete proof of the purity of any algal culture from all bacteria, the 'positive operator bias' technique appears to increase the chances of success by at least one order of magnitude without engendering serious metabolic disturbance. It has been employed successfully in this laboratory, to provide bacteria-free cultures of two *Anabaena*, two *Polycystis*, two brown *Oscillatoria* and four green *Oscillatoria*. It is being used routinely in this laboratory for the bacteria-free isolation of other types of algae which may be of interest. This work was done in co-operation with the National Aeronautics and Space Administration.

### Inhibition of Growth of *Aerobacter aerogenes* by Sodium Chloride

SODIUM chloride is usually added to a culture medium to make the medium isotonic, so that any blood added as an enrichment is not haemolysed. It is conceivable that any specific requirements a non-marine bacterium might possess for the Na<sup>+</sup> or the Cl<sup>-</sup> ion is so small it can be supplied by the culture medium itself. Thus, the addition of sodium chloride, at a concentration of 0.5 per cent (w/v), to any medium intended for the growth of non-marine bacteria seems arbitrary unless it has previously been shown to be necessary to promote optimal growth or to demonstrate some particular metabolic activity (for example, haemolysis).

Certain bacteria can tolerate relatively high concentrations of sodium chloride. For such salt-tolerant bacteria the term 'halophilic' has been adopted. This characteristic is not an expression of a specific requirement for sodium chloride, but of an acquired ability to tolerate high salt concentrations. Marine bacteria, particularly *Halobacterium* species, require a concentration of 1.0 per cent (w/v) of sodium chloride before growth can take place in a liquid medium<sup>1</sup>. Agar-liquefying pseudomonads do not exhibit agarase activity until 2.4 per cent (w/v) sodium chloride is present in a nutrient agar<sup>2</sup>.

Few reports of the 'inhibitory effects' of 0.5 per cent (w/v) sodium chloride appear to have been made. Indeed, the widespread use of this concentration of this electrolyte would lead one to believe that its inclusion in a medium is essential or even beneficial to the growth of bacteria. During some growth experiments on *Proteus*<sup>3</sup> (in a medium containing 0.5 per cent (w/v) peptone 0.3 per cent (w/v) 'Lab-Lemco' meat extract), it was noted that *Aerobacter aerogenes* produced less growth when 0.5 per cent (w/v) sodium chloride was added to the medium than when grown in the absence of sodium chloride. As a result of this it was decided to examine the effect more closely. The methods and experimental techniques used were those described previously<sup>3</sup>.

From the growth curve (Fig. 1) over a 24-h incubation period at 37° C it will be seen that sodium chloride exerts a growth depressant effect on *A. aerogenes* N.C.T.C.

Fig. 1. Growth curves of *E. coli* N.C.T.C. 4144 in broth (Δ) and broth plus sodium chloride (▲) compared with growth curves of *A. aerogenes* N.C.T.C. 8172 in broth (○) and broth plus sodium chloride (●)

Fig. 2. Growth of *A. aerogenes* N.C.T.C. 8172 (●) and *Proteus vulgaris* 7149 (○) at 37° C, over a range of sodium chloride concentrations

8172 over the entire incubation period. In contrast to this the growth of *E. coli* N.C.T.C. 4144 is unaffected by the presence of sodium chloride. The effect of variations in sodium chloride concentrations on *A. aerogenes* N.C.T.C. 8172 and *Proteus vulgaris* 7149 is shown in Fig. 2. At no concentration of sodium chloride is the growth of *A. aerogenes* greater than growth obtained in the absence of sodium chloride whereas *Proteus* gives a peak of growth at a concentration of 0.5 per cent sodium chloride.

The apparent growth inhibition of *A. aerogenes* by sodium chloride may be due to membrane instability associated with cation dependency<sup>1</sup>. Wyatt<sup>4,5</sup> has postulated that the inhibition of growth of staphylococci by cations could be a function of the transport of certain cations which antagonize certain metabolic pathways, for example, pyruvate phosphokinase is antagonized by sodium or calcium ions. Mechanisms of this sort could play a part in the phenomenon described here. Whatever the underlying cause of this effect it would appear that sodium chloride has an inhibitory effect on *A. aerogenes*. This effect should be borne in mind when carrying out

cultural procedures with this organism. Furthermore, such an effect makes one question the validity for the use of sodium chloride at its 'classical' concentration.

## VIROLOGY

### Role of Temperature and Light in Lesion Development of Tobacco Mosaic Virus

THE optimum post-inoculation temperature for the development of macroscopic lesions of the common strain of tobacco mosaic virus (TMV) on *Phaseolus vulgaris* L. var. 'Pinto' is about 31° C, whereas for the sweet potato strain it is 16° C or lower<sup>1</sup>. This report describes the effects of post-inoculation temperatures of 20°, 25° and 30° C, and light intensities of 640 ft.-candles and 4,000 ft.-candles on the development of macroscopic lesions and the total number of detectable lesions (starch lesions)<sup>2</sup> by three further strains of TMV: 'U<sub>1</sub>', which is an example of the common strain of TMV and is well known to form lesions on Pinto bean leaves, 'U<sub>2</sub>' (ref. 3), which is reported

Fig. 2. Effect of temperature and high light intensity (4,000 ft.-candles) on size of lesions (starch lesions) formed by strains of TMV on Pinto bean leaves. Mean data for one experiment. Numbers of lesions measured at 20°, 25° and 30° C were: 168, 283 and 218 for U<sub>1</sub>; 354, 379 and 168 for U<sub>2</sub>; 265, 256 and 115 for VM.

to form lesions on this host by some authors<sup>2,4,5</sup>, but not by others<sup>3-9</sup>, and 'VM' (ref. 10), which previously was not known to form lesions on this host<sup>8,9</sup>.

The Pinto bean seed was obtained from the Haney Seed Co., Twin Falls, Idaho. It was grown in Ceres, the Canberra phytotron, in vermiculite watered once daily with Hoagland's nutrient solution and once with demineralized water. In the first set of experiments, the seeds were germinated (during the winter) in naturally lit bays maintained at a day temperature of 27° and a night temperature of 22° C. Six days after sowing the seedlings were put in artificially lit cabinets at 25° C with an 8-h photoperiod of 4,000 ft.-candles (fluorescent and incandescent light). Three days later they received a pre-inoculation dark period of 24 h followed by 1.5-2 h light at 4,000 ft.-candles before inoculation. There were 10 plants for each treatment in each experiment. U<sub>1</sub> was applied at 0.4 µg/ml., and U<sub>2</sub> and VM at 2.5 or 10 µg/ml. The primary leaves were inoculated with a brush using 0.1 M phosphate buffer at pH 7.0 and 5 per cent 'Celite'. After inoculation, the plants were placed for 72 h in cabinets run at 20°, 25° or 30° C with continuous light of 4,000 ft.-candles. This was followed by 24 h darkness at the same temperatures. The inoculated leaves were then gathered and stored in the dark at 25° C for an additional 24 h to remove excess starch before lesions were counted and measured on leaf disks sampled from leaves<sup>3</sup>. Data for the numbers and size of lesions in each treatment are shown in Figs. 1 and 2, respectively. With U<sub>1</sub>, the number of both classes of lesions increased with increase in temperature; with U<sub>2</sub> and VM the number of macroscopic lesions decreased with increase in temperature, whereas the number of starch lesions reached a maximum at 25° C. Lesions of U<sub>1</sub> were larger than those of U<sub>2</sub>, which in turn were larger than those of VM. For each strain, the patterns for size of lesions in relation to temperature showed similar trends to those for numbers of macroscopic lesions.

In a further set of experiments, inoculated plants were incubated at the same temperatures but with a light intensity of 640 ft.-candles. The pre-inoculation environ-

Fig. 1. Effect of temperature and high light intensity (4,000 ft.-candles) on numbers of lesions formed by strains of TMV on Pinto bean leaves. Mean data for 3 experiments. For each treatment of each experiment lesions were counted on two 18 mm leaf disks sampled from each of 20 leaves. For each strain, numbers of macroscopic and starch lesions at 25° C and 30° C were adjusted relative to the number of macroscopic lesions at 20° C, 100. Numbers of lesions were then adjusted for variation of leaf area with temperature.

## GENETICS

## Antimutagenic Effect against Colchicine of Kinetin in Black Currant Seedlings

It is generally known that the juvenility of plant organs can be prolonged by treatment with kinetin; moreover, senescent tissues can be rejuvenated<sup>1</sup>, and several authors have shown increased mutability of older tissues<sup>2</sup>. Treatment of plant leaves by kinetin appreciably inhibits the multiplication of viruses<sup>3</sup>, although the virus contains RNA. After incorporation into the host cells, the virus may cause information disturbances by inducing the synthesis of foreign RNA. In this interpretation, the changes brought about by the virus are in the nature of mutations.

On this basis we have supposed that kinetin has an antimutagenic activity, or, in other words, that it takes part in the protection of the information-system controlling heredity. In order to test this idea, we attempted to neutralize the genome mutation-inducing effect of colchicine by pre-treatment of the plant with kinetin.

We chose black currant ('Altayskaya Desertnaya' × 'Boskoop Giant' *F*<sub>1</sub> seedlings) as a test plant. The treatment of the shoots of the seedlings by kinetin (50 p.p.m. or by kinetin (50 p.p.m.) + colchicine (0.8 per cent) was started at the 3-4 leaf age in the greenhouse, and was continued for 24 days, repeating the treatment daily. Following this, a solution of colchicine (0.8 per cent) and gibberellic acid (GA; 50 p.p.m.) was applied to the shoot of the plants for a period of 21 days, twice a day using the 'cotton cup' method. Colchicine was added to gibberellic acid because in earlier experiments we obtained a much higher percentage of genome mutation by applying this technique than by the use of the classical colchicine treatment<sup>4</sup>. Evaluation was made by the 'squash' technique, using fixed shoots 5 days after finishing the treatment.

Table 1. ANTAGONIZING EFFECT OF PRETREATMENT BY KINETIN ON THE GENOME MUTATION OF BLACK CURRANT SEEDLINGS INDUCED BY COLCHICINE

Pretreatment	Mutagenic treatment	No. plants	Mixoploids No.	%
—	Colchicine + GA	44	12	27.3
Kinetin	Colchicine + GA	55	0	0.0
Kinetin + colchicine	Colchicine + GA	48	13	27.0

The pre-treatment with kinetin provided a complete protection against the mutagenic treatment, without influencing the growth of the seedlings. It seems, however, that a longer time is needed for the realization of the stabilizing effect of kinetin, since colchicine applied together with kinetin—as a pre-treatment—has inhibited the stabilization.

In the past, a number of publications have reported the natural occurrence of kinetin-like substances<sup>5</sup>. Thus, it is possible that these substances play a part in stabilizing the transfer of genetic information. This view is supported by the results of Matthews<sup>6</sup>, who has shown the presence of RNA-attached purine derivatives and attributed a stabilizing role to these compounds.

mental conditions were unchanged except that the plants were grown (during the summer) under net shades with natural lighting, until 24 h before inoculation when they were placed in the dark at 25° C; the plants then received a light intensity of less than 10 ft.-candles for 1.5 h before they were inoculated. Lesions were counted immediately after leaves were gathered. For U<sub>1</sub> and U<sub>2</sub>, the patterns for the numbers of macroscopic and starch lesions which developed at 20°, 25° and 30° C and 640 ft.-candles (Table 1) resembled those at 4,000 ft.-candles (Fig. 1); for VM, no macroscopic lesions were formed and starch lesions were not identified consistently. In these experiments lesions of all strains were smaller and contained less starch than those in the previous experiments. This made lesions of U<sub>2</sub> and VM more difficult to identify than in the previous experiments, especially when the inoculated plants were incubated at 30° C. In a previous paper, it was shown that the ratio of the numbers of macroscopic lesions to the numbers of starch lesions could be used as a measure of lesion size<sup>2</sup>. In the present experiments, in plants inoculated with U<sub>1</sub> and U<sub>2</sub> and incubated at 25° C and 640 ft.-candles, this ratio was 36.0 per cent and 0.2 per cent, respectively, whereas in plants incubated at 25° C and 4,000 ft.-candles it was 68.4 per cent and 4.7 per cent respectively. This difference between the size of lesions in the two sets of experiments is considered to be due primarily to the light intensity used for the incubation of inoculated plants. It may be due in part to the light intensity the plants received immediately before inoculation.

Table 1. EFFECT OF TEMPERATURE AND LOW LIGHT INTENSITY (640 FT.-CANDLES) ON NUMBERS OF LESIONS FORMED BY STRAINS OF TMV ON PINTO BEAN LEAVES\*

Virus strain	Class of lesions	Temperature of incubation (°C)		
		20	25	30
U <sub>1</sub> †	Macroscopic	100	239	327
	Starch	263	699	747
U <sub>2</sub> ‡	Macroscopic	100	2	0
	Starch	693	1,160	995
VM‡	Macroscopic	0	0	0
	Starch	§	§	§

\* Numbers of lesions were adjusted in the same way as those in Fig. 1.

† Mean data for 2 experiments.

‡ Mean data for 3 experiments.

§ Occasional lesions recognized.

The experiments show that the patterns of number and size of lesions, in relation to post-inoculation temperature, vary with different virus strains and that the size of lesions is affected by light intensity. In several investigations made to examine the phenomena of interference and heat activation, U<sub>2</sub> and VM were not observed to form lesions on Pinto bean plants given environmental conditions, suitable for the development of lesions of U<sub>1</sub> (refs. 6-9). The temperature used for the incubation of inoculated plants was 30° C and the light intensity was 400 or 500 ft.-candles. The present results indicate that although these conditions are favourable for the development and identification of lesions of U<sub>1</sub>, they are relatively unfavourable for the development and identification of lesions of U<sub>2</sub> and VM.

I thank Mrs. E. Valtas for her assistance.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, January 25

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.E./I.E.R.E. COMPUTER GROUPS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 10.30 a.m.—Colloquium on "Logic Circuits".

UNIVERSITY COLLEGE, LONDON (in the Botany Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. P. N. Magee: "The Biochemical Pathology of Intracellular Alkylating Reactions".\*

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. Hyden (Göteborg): "Molecular Biology Studies in the Nervous System".\*

UNIVERSITY OF LONDON (in the Physiology Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. H. Hubel (Harvard Medical School): "The Eye, The Brain and Perception" (further lectures on January 27 and 29).\*

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—discussion on "The Problem of Obtaining Training Places for Six-Month Sandwich Course Students".

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Mr. J. Hardwood: "Flame Retardant Processes".

## Tuesday, January 26

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Short Paper Meeting.

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (Joint I.E.E./I.E.R.E. meeting at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 3 p.m.—Colloquium on "The Achievement of High Accuracy in Analogue to Digital Conversion".

UNIVERSITY OF LONDON (in the New Lecture Theatre, Wye College, near Sharnford, Kent), at 4.30 p.m.—Dr. G. A. Pitt: "Recent Advances in the Physiology of Vitamin A".\*

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE (at Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Prof. P. J. O. Self: "Bureaucracy or Management?".\*

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. L. J. Lawler: "The British Contribution to Educational Television in the Commonwealth" (Sir Thomas Holland Memorial Lecture).

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, W.1), at 5.30 p.m.—Mr. E. R. Bryan and Mr. W. M. El-Dakhkhni: "The behaviour of Sheeted Portal Frame Sheds. Part 1—Theory. Part 2—Experiments".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. N. J. Felici: "Electrostatic Generators".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. R. King: "Electrons in Solids". (Afternoon lecture for Sixth Form boys and Girls in Schools from London and the Home Counties. To be repeated on January 27, February 2 and 3.)

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 3.30 p.m.—Prof. Victor Gold: "Analysing Chemistry" (Inaugural Lecture).\*

UNIVERSITY OF LONDON (at the Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. Stanley Gill: "Automatic Computing; its Problems and Prizes" (Inaugural Lecture).\*

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. L. Goldberg: "New Outlook in Toxicology". (Fourth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. E. W. Abrahamson (Case Institute of Technology, Cleveland): "The Macromolecular Aspects of Vision".\*

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINES GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—discussion on "Running-In of Diesel Engines".

## Wednesday, January 27

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 2 p.m.—Dr. A. J. Grimes: "Metabolism of Red Cells".\*

FAUNA PRESERVATION SOCIETY (at the Offices of the Zoological Society of London, Regent's Park, London, N.W.1), at 5.30 p.m.—Dr. E. J. H. Corner, F.R.S.: "The Mt. Kinabalu National Park in North Borneo".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Protection Problems associated with Marine Electrical Systems" opened by Dr. J. R. Mortlock and Mr. W. C. Robertson.

CHALLENGER SOCIETY (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 5.45 p.m.—Mr. R. Gambell: "Current Research upon Whales at Durban".

ASSOCIATION OF THE WILLIAM PENGELLY CAVE RESEARCH CENTRE, in conjunction with Imperial College Caving Club (in the Physics Department, Imperial College, London, S.W.7), at 6 p.m.—Dr. Trevor Ford: "The Fossil Earst in Derbyshire".\*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, RADAR GROUP (at Bedford Square, London, W.C.1), at 6 p.m.—Symposium on "Enhancement and Absorption of Radar Radiation".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Vice-Admiral R. S. Hawkins: "Progress in Naval Machinery During the Last Thirty Years" (Thomas Lowe Gray Lecture).

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Mr. A. S. Basford and Mr. S. S. Brown: "Automatic Vending".

ROYAL AERONAUTICAL SOCIETY, GRADUATES' AND STUDENTS' SECTION (at 4 Hamilton Place, London, W.1), at 7.30 p.m.—Mr. S. R. Hughes: "Hovercraft".

## Thursday, January 28—Friday, January 29

CHALLENGER SOCIETY, AND REPRESENTATIVES FROM THE MARINE LABORATORIES (Development Commissioners' Scheme) (in the Meeting Room of the Zoological Society of London, Regent's Park, London, N.W.1), at 10.15 a.m. daily—Symposium on "The Movement of Sediments on the Sea Floor and Their Significance to Benthic Animal Communities".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 10.30 a.m. daily—Discussion Meeting on "Recent Advances in the Technique of Seismic Recording and Analysis" organized by Sir Edward Bullard, F.R.S., and Sir William Penney, F.R.S.

## Thursday, January 28

INSTITUTION OF AGRICULTURAL ENGINEERS (at the Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1), at 10.15 a.m.—Mr. J. B. Holt: "The Handling of Unit Loads in Agriculture and Horticulture"; Mr. R. D. Hall: "Work Study in the Mechanization of Farming"; Mr. H. C. Green: "The Susceptibility of Fruit and Potatoes to Damage during Handling".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Standard Methods of Measurement of Civil Engineering Work" introduced by Mr. A. Goldstein.

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. D. Noble: "Biophysics of Cardiac Muscle". (Fifth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

UNIVERSITY OF LONDON (at the School of Pharmacy, 29-39 Brunswick Square, London, W.C.1), at 5.30 p.m.—Prof. F. Sandberg (Stockholm): "The Effect of Various Drugs on the Human Uterus".\*

## Friday, January 29

ROYAL AERONAUTICAL SOCIETY, ROTOCRAFT SECTION (at 4 Hamilton Place, London, W.1), at 2.15 p.m.—Dr. I. C. Cheeseman: "Powered Lift Applications in the Commonwealth"; Mr. W. A. Hibbert: "Helicopter Trials on Sand and Sea".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. G. F. Tagg: "Measurement of Earth Electrode Resistance with particular reference to Earth Electrode Systems covering a Large Area".

UNIVERSITY OF LONDON (at the School of Pharmacy, 29-39 Brunswick Square, London, W.C.1), at 5.30 p.m.—Prof. F. Sandberg (Stockholm): "Arrow Poisons—Their Origin, Chemistry and Action".\*

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. R. L. Gregory: "Seeing in Depth".

## Saturday, January 30

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. Norman Cook: "Unearthing London's History".\*

## Monday, February 1

SOCIETY OF ENGINEERS (in the Apartments of the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Inaugural Meeting for the year 1965. Mr. C. L. N. Laing: Presidential Address.

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Members' Discussion of "The Society's Publications". Discussion Leader: Prof. W. G. Overend.

INSTITUT FRANCAIS DU ROYAUME-UNI (at Queensberry Place, South Kensington, London, S.W.7), at 8.15 p.m.—French Scientific Films.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SCIENTIFIC LIAISON OFFICER (with a university degree in science) at Long Ashton Research Station, to be responsible for organizing public functions, making arrangements for receiving visiting scientists and for editing the Station's Annual Report—The Registrar, University of Bristol, Senate House, Bristol, 2 (January 30).

SENIOR LECTURER, a LECTURER and an ASSISTANT LECTURER in PURE MATHEMATICS—The Secretary, The University, Aberdeen (January 30).

LECTURER/ASSISTANT LECTURER IN PHILOSOPHY—The Principal, St. David's College, Lampeter, Cardiganshire (January 31).

ASSISTANT LECTURER IN HISTORICAL GEOGRAPHY—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (February 1).

LECTURER or ASSISTANT LECTURER (with an honours degree in engineering or physics and experience in industrial acoustics) in INDUSTRIAL ACOUSTICS—The Deputy Secretary, The University, Southampton (February 1).

ASSISTANT LECTURER IN PSYCHOLOGY—The Secretary, The Queen's University, Belfast, Northern Ireland (February 5).

LECTURER or an ASSISTANT LECTURER IN STATISTICS—The Registrar (Room 22, O.R.B.), The University, Reading (February 5).

LECTURER or an ASSISTANT LECTURER (with qualifications in pure mathematics) in MATHEMATICS—The Registrar, The University, Keele, Staffs (February 5).

LECTURER or SENIOR LECTURER IN CLINICAL EPIDEMIOLOGY IN THE DEPARTMENT OF INFECTIOUS DISEASES at Ruchill Hospital—The Secretary of the University Court, The University, Glasgow (February 5).

LECTURERS (2) (mathematicians) IN THE DEPARTMENT OF THEORETICAL MECHANICS (Faculty of Engineering)—The Registrar, University of Bristol, The Senate House, Bristol, 2 (February 5).

ASSISTANT IN AGRICULTURAL BOTANY—The Secretary of the University Court, The University, Glasgow (February 6).

LECTURERS or ASSISTANT LECTURERS (2) (graduates with an honours degree in chemistry, biochemistry or agricultural chemistry) IN THE DEPARTMENT OF AGRICULTURAL SCIENCES—The Registrar, The University, Nottingham (February 6).

PROFESSOR OF MATERIALS SCIENCE—The Registrar, Ref. 72Y/X, Bradford Institute of Technology, Bradford, 7 (February 8).

READER IN STATISTICS—The Secretary, Trinity College (University of Dublin), Dublin 2, Republic of Ireland (February 9).

ASSISTANT LECTURER IN THE DEPARTMENT OF AGRICULTURAL BOTANY—The Registrar, University College of North Wales, Bangor, North Wales (February 10).

ASSISTANT LECTURER (with qualifications in any branch of genetics) IN GENETICS—The Registrar, The University, Sheffield (February 13).

CHAIR OF THEORETICAL MECHANICS AND HEAD OF THE DEPARTMENT—The Registrar, The University, Nottingham (February 15).

LECTURER (preferably with an interest in X-ray techniques or geochemistry or metamorphic petrology) IN GEOLOGY IN GEOLOGY (Room 22, O.R.B.), The University, Reading (February 16).

LECTURER or ASSISTANT LECTURER (with qualifications in plant physiology or in mycology with a physiological background) IN BOTANY; and a LECTURER or ASSISTANT LECTURER (qualified in the field of general zoology) IN ZOOLOGY at the University of Basutoland, Bechuanaland Protectorate and Swaziland—The Secretary Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (February 20).

LECTURER (preferably with experience in the field of fisheries biology, either freshwater or marine, or of experimental zoology) IN THE DEPARTMENT OF ZOOLOGY, University of Ghana—The Assistant Registrar, University of Ghana Overseas Office, 15 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (February 24).

LECTURER (preferably with qualifications in structural geology, geophysics and/or economic geology) IN THE DEPARTMENT OF GEOLOGY, University of Ghana—The Assistant Registrar, University of Ghana Overseas Office, 15 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (February 24).

SENIOR LECTURER and a LECTURER IN THE DEPARTMENT OF PHYSICS, University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (February 24).

LECTURER or an ASSISTANT LECTURER IN THE DEPARTMENT OF GEOGRAPHY, University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (February 27).

LECTURER or ASSISTANT LECTURER (preferably with industrial experience and research interests in the field of aircraft propulsion) IN AERONAUTICAL PROPULSION—The Deputy Secretary, The University, Southampton (February 27).

LECTURERS (2) (with special interests in either soil mechanics or municipal engineering) IN CIVIL ENGINEERING—The Deputy Secretary, The University, Southampton (February 27).

CHAIR OF STATISTICS WITHIN THE DEPARTMENT OF MATHEMATICS—The Registrar, The University, Nottingham (March 1).

JUNIOR RESEARCH ASSOCIATE IN THE DEPARTMENT OF BOTANY to work on the metabolism and enzymology of aromatic ring fusion in moulds and yeasts—The Registrar, The University, Newcastle upon Tyne, 1 (March 1).

LECTURER/SENIOR LECTURER IN BIOLOGY (in the field of Statistical Plant Ecology) IN THE SCHOOL OF BIOLOGICAL SCIENCES, University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, March 1).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS (preferably with a Ph.D. or equivalent research experience, and below the age of 30) IN BIOCHEMISTRY, CHEMISTRY, ENGINEERING, GEOLOGY, or PHYSICS—The Registrar, The University, Leicester (March 6).

ENTOMOLOGIST (national of the United Kingdom or the Republic of Ireland, with a degree in biology and at least two years' postgraduate research) with the East African Common Services Organization, to study ways for improving methods of controlling or eradicating tsetse flies by insecticides and chemical sterilants including both laboratory and field studies—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/214/07.

FISHERIES OFFICER (national of the United Kingdom or the Republic of Ireland, with a good science degree and experience of fisheries management, including marketing and processing) in Malawi, to collect statistics and develop and demonstrate to local fishermen improved methods of fishing appropriate to local conditions—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 289/134/01.

HEAD OF THE MATHEMATICS DEPARTMENT—Grade IV—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

JUNIOR RESEARCH ASSOCIATE (graduate with suitable qualifications) for research on heat and water transfer over cold surfaces—The Registrar, The University, Newcastle upon Tyne, 1.

LECTURER (colloid chemist, preferably with experience of rubber latex and/or synthetic dispersions and emulsions); and a LECTURER (polymer technologist with a knowledge of the chemistry and applications of rubbers and/or thermoplastics)—Clerk to the Board of Governors, National College of Rubber Technology, Northern Polytechnic, Holloway, London, N.7.

LECTURER IN THE CRIPS COMPUTING CENTRE—The Registrar, The University, Nottingham.

RESEARCH ASSISTANT (preferably with a knowledge of Spanish) IN THE GEOGRAPHICAL RESEARCH DIVISION, for work in the field of economic geography of Latin America with special reference to energy—Dr. J. E. Martin, London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2.

RESEARCH ASSISTANT (with a Ph.D. or equivalent research experience and some knowledge of electronics) for group centred at Silwood Park, near Ascot, working on rocket measurements of magnetic fields in the ionosphere, currently concerned with Centaur and Skylark rockets launched from Woomera and Andoya Is.—The Geophysics Department, Imperial College, London, S.W.7.

STATE FOREST OFFICER (male, not over 45, with an honours degree in forestry plus at least five years' tropical experience) in Brunei, to be in charge of the Forestry Department, be responsible for the enforcement of the Forest Enactment and rules designed to protect the forests, manage and

develop forests, train field staff and give general advice on the proper utilization of timber—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 324/28/01.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

The Nuffield Foundation Science Teaching Project. Progress Report, October 1964. Pp. 31. (London: Longmans, Green and Co., Ltd.; and Penguin Books, 1964. Published for the Nuffield Foundation.) [2511]

British Antarctic Survey. Scientific Reports, No. 45: The Vascular Flora of South Georgia. By Dr. S. W. Greene. Pp. 58+31 maps+6 plates. (London: British Antarctic Survey, 1964.) 32s. net. [2511]

Royal Holloway College. Descriptive Brochure. Pp. 24. (Englefield Green: Royal Holloway College, 1964.) [2511]

The Association of Commonwealth Universities. Annual Report of the Council, together with the Accounts of the Association for the year 1st August 1963 to 31st July 1964. Pp. 46. (London: The Association of Commonwealth Universities, 1964.) [2511]

Philosophical Transactions of the Royal Society of London. Series A: Mathematical and Physical Sciences. No. 1075, Vol. 256 (12 November 1964): The Volcanological Report of the Royal Society Expedition to Tristan da Cunha, 1962. By P. E. Baker, I. G. Cass, P. G. Harris and R. W. Le Maitre. With appendixes by M. W. Holdgate, J. H. Dickson, D. B. Baird, J. A. Miller and K. M. Creer. Pp. 439-578+plates 16-33. 90s.; 13.50 dollars. Series B: Biological Sciences. No. 742, Vol. 247 (19 November 1964): The Cranial Anatomy of Two Coal Measure Anthracosaurs. By A. L. Panchen. Pp. 593-637+plate 10. 20s.; 3 dollars. (London: The Royal Society, 1964.) [2511]

### Other Countries

United States Department of the Interior: Geological Survey. Bulletin 1194-B: The Hovey Group of Northeastern Maine. By Louis Pavlides. Pp. iii+6. Bulletin 1194-C: The Putnam Group of Eastern Connecticut. By H. Roberta Dixon. Pp. iii+12. Water-Supply Paper 1586-F: On Determining Pollutant Distribution in Tidal Estuaries. By E. E. Pyatt. Pp. iv+56+plates 1 and 2. Water-Supply Paper 1613-D: Relation of Salt-Water Encroachment to the Major Aquifer Zones, Savannah Area, Georgia and South Carolina. By M. J. McCollum and H. B. Counts. Pp. iv+26+plates 1-4. Water-Supply Paper 1698: Ground-Water Resources and Geology of Northern and Western Crook County, Wyoming. By Harold A. Whitcomb and Donald A. Morris. Pp. v+92+plates 1 and 2. Water-Supply Paper 1735: Compilation of Records of Surface Waters of the United States, October 1950 to September 1960. Part 2: Pacific Slope Basins in California. Prepared under the direction of E. L. Hendricks. Pp. xvi+715+plate 1. Water-Supply Paper 1748: Apparatus and Techniques for Measuring Bedload. By D. W. Hubbell. Pp. v+74. Water-Supply Paper 1753: Geology and Ground-Water Resources of the Los Alamos Area, New Mexico. By Roy Griggs. With a section on Quality of Water by John D. Hem. Pp. v+107+plate 1. (Washington, D.C.: Government Printing Office, 1964.) [2611]

United States Department of the Interior: Geological Survey. Water-Supply Paper 1779-H: Ground Water in Cedar Rapids Division of Lower Plate River Basin, Nebraska. By James B. Hyland and Charles F. Keech. With a section on Chemical Quality of the Water by Philip G. Rosene. Pp. iii+12+plates 1-3. Water-Supply Paper 1779-O: Hydrology of Aquifer Systems in the Memphis Area, Tennessee. By J. H. Criner, P.-C. P. Sun and D. J. Nyman. Pp. v+54+plates 1-7. Water-Supply Paper 1779-V: Ground Water Resources of Eastern Arkansas in the Vicinity of U.S. Highway 70. By H. N. Halberg and J. E. Reed. Pp. iv+38+plates 1-4. Water-Supply Paper 1783: Hydrologic Conditions in the Wheatland Flats Area, Platte County, Wyoming. By Edwin P. Weeks. Pp. v+79+plates 1-8. (Washington, D.C.: Government Printing Office, 1964.) [2611]

United States Department of the Interior: Geological Survey. Professional Paper 383-B: Geologic Factors That Control the Occurrence and Availability of Ground Water in the Fort Rock Basin, Lake County, Oregon. By E. R. Hampton. Pp. iii+29+plate 1. Professional Paper 411-H: Mathematics of Dispersion With Linear Adsorption Isotherm. By Akio Ogata. Pp. iii+9. Professional Paper 454-M: Bedrock Valleys of the New England Coast as Related to Fluctuations of Sea Level. By Joseph E. Upson and Charles W. Spencer. Pp. iv+44+plates 1-5. Professional Paper 458-A: Regional Geology of the Steamboat Spring Area, Washoe County, Nevada. By G. A. Thompson and D. E. White. Pp. iv+52+plates 1 and 2. (Washington, D.C.: Government Printing Office, 1964.) [2611]

Smithsonian Miscellaneous Collections. Vol. 146, No. 5: Some Behavior Patterns of Platyrrhine Monkeys. 1: The Night Monkey (*Aotus trivirgatus*). By M. Moynihan. Pp. 84. (Publication 4533.) Vol. 146, No. 7: A New Species of Marine Pennate Diatom from Honolulu Harbor. By Paul S. Conger. Pp. 5. (Publication 4593.) Washington, D.C.: Smithsonian Institution, 1964.) [2611]

The Smithsonian Institution. Masters of Space. By Philip S. Hopkins. Pp. 32. (Washington, D.C.: Smithsonian Institution, 1964.) [2611]

National Science Foundation. Programs for Improving the Dissemination of Scientific Information. Pp. 15. (NSF-64-22.) (Washington, D.C.: National Science Foundation, 1964.) [2611]

# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

- AUTOMATIC** interchange of up to 4 sample and 4 reference cells
- AUTOMATIC** re-cycling over any preselected wavelength range
- AUTOMATIC** recordings at predetermined time intervals.

*Please send for descriptive brochure*

*Save operator time, increase speed and efficiency with Unicam automation for:*

**ENZYME REACTION RATES**

**LIQUID COLUMN CHROMATOGRAPHY**

**ALL ROUTINE ULTRAVIOLET AND  
VISIBLE SPECTROSCOPY**

# AGAROSE

A neutral galactose polymer obtained from Agar by a unique method using reagents having no toxicity.

- \* Negligible electroendosmotic properties.
- \* High gel strength.
- \* Non-toxic.
- \* Minimum adsorption properties.

This product and many ENZYMES and RELATED BIOCHEMICALS of the highest possible integrity are produced entirely in our own laboratories.

PRECISION INSTRUMENTS

## Spectrometer No. 2

Fitted with a variable half shadow polariser on the collimator, and an analyser with detachable quarter wave plate on the telescope.

Rack and pinion focusing.

Both polarising attachments are quickly removable to permit use as a conventional spectrometer.

Micrometer eyepiece to the scale reader enables direct measurement of angle to 10 secs.

*For further details of this instrument, also of polarimeters and refractometers, please write to Dept. N*

# Sir Winston Churchill

K.G., O.M., C.H., F.R.S.

SIR WINSTON CHURCHILL, whose death we mourn, was the first British Prime Minister to appreciate the importance of science and technology to our country. His interest and appreciation were of enormous importance in the conduct and outcome of the Second World War. It was fostered by his friendship with Prof. F. A. Lindemann, which started in 1921 on one of Lindemann's social visits, and led to discussions on the scientific interests of 'The Prof.', who was also able to advise on the hydraulic problems of the new water gardens being built at Chartwell—Churchill hoping that "the problems were not beyond Oxford mathematics".

In the 1930's, as a result of this friendship, Churchill began to take a close interest in the problems of air defence and particularly in the applications of radar, and this led, in turn, to the appointment of Lindemann to Sir Henry Tizard's "Scientific Committee on Air Warfare", an appointment which led to the difficulties on the Committee which have already been sufficiently described. In June 1939 he was conducted by Tizard "in a rather disreputable aeroplane" on a tour of the radar establishments on the East Coast. He told the Air Minister that he found his visits to Martlesham and Bawdsey profoundly interesting, and urged the importance of radar to the Navy—"I cannot conceive", he said, "why the Admiralty are not now hot upon this trail".

He became First Lord of the Admiralty in 1939 and was then in a position to press his views, and, in particular, the need for improving radar installations. This led, no doubt, to Admiral Sir James Somerville's urgent demand in September 1939 for the immediate installation around Scapa Flow of radar sets to detect low-flying aircraft. As a result, a team of physicists from the universities, helped by industry and Government establishments, completed the installation of the "C.D.U." radar stations at Sumbrough Head in early December 1939 and on Fair Isle by February 1940. Without the drive from the top, this rapid work would have been impossible.

Sir Winston also founded a Statistical Office with Prof. Lindemann in charge, and a team of six economists was very speedily installed under the leadership of G. D. A. MacDougall. This later became the Prime Minister's statistical section, which provided him with speedy and direct information through charts and an endless stream of minutes from 'The Prof.' on quantitative aspects of the conduct of the War.

As the bombing attack on Britain developed in 1940, the Prime Minister took a still more intense interest in the application of radar. His minute of October 25, 1940, directed that "The very highest priority in personnel and materials should be assigned to what might be called the radio sphere. We must impart a far higher accuracy to the A.A. guns and a far better protection to our warships and harbours".

Eight months earlier the high-power centimetre cavity magnetron had been born in the Physics Laboratories of the University of Birmingham, and by May 1940 centimetre radar was operating in a primitive way on the Downs above Worth Matravers and, with unparalleled rapidity, centimetre radar sets were installed in ships and aeroplanes. It was not unusual for scientists directing the experimental teams to be summoned to the presence of the Prime Minister, dressed in his boiler suit, to be

interviewed about the progress of their work and commanded to bring the latest devices into operation "by the next moon phase".

The Prime Minister was responsible for authorizing the Tizard Mission to proceed to the United States in September 1940 to disclose all our scientific war secrets to the United States authorities. Fortified by his blanket instructions, the Mission got together the famous "black box" collection of samples, reports, drawings, including a working centimetre magnetron. The Mission was successful in establishing complete scientific collaboration and led to the foundation of the successful Radiation Laboratory at the Massachusetts Institute of Technology, which developed centimetric radar for the U.S. forces and provided a great deal of equipment for Britain at critical times.

The Mission also established collaboration with the United States on atomic energy developments, and reports on the work being carried out in Britain under the auspices of the MAUD Committee were rapidly transmitted. This Committee's final report of July 1940 led to a great intensification of work on the atomic bomb by the United States. Personal intervention by Sir Winston led to the Quebec Agreement which enabled British scientists to make an important contribution to the joint war effort, and also enabled them to develop, through the Canadian-U.K. Chalk River project, an almost complete knowledge of nuclear reactor technology.

In the later stages of the War, the Prime Minister took a personal interest in the threat of the flying bomb and the V.2 rocket. There were at times differences of opinion between Lord Cherwell and other scientists advising the Prime Minister, and it was not unusual for him to convene a meeting of the protagonists and responsible Ministers and to insist on the scientists being allowed to give their direct views.

After Sir Winston's retirement from office in 1955, he decided to devote a large part of his remaining energy to awakening Britain to the importance of improving her scientific and technological education. Out of this interest emerged the concept of the foundation of Churchill College with the objective of increasing the supply of highly trained scientists and technologists. It was to have a student body of 540—one-third of them to be postgraduates and 70 per cent working in science and technology. Sir Winston became chairman of the Trustees, who collected the funds for the greater part of the building and endowment of the College. The College reflects Sir Winston's world-wide interest by having more than 60 overseas graduate students and up to 10 Fellows from overseas in an academic year.

In a statement, after the death of Sir Winston, the Right Hon. Harold Wilson said that "Details will be announced shortly by Field Marshal Lord Alexander of plans for an appeal which is being organized on an international basis by close friends and colleagues of Sir Winston Churchill. Sir Winston Churchill himself regarded Churchill College as his national memorial, and the new appeal will enable the public in this country and abroad to show their respect for his memory by contributing further to that foundation and to other similar causes which the organizers will announce in due course."

JOHN COCKCROFT

## SCIENTIFIC POLICY-MAKING IN BRITAIN

THE paper on "Government Scientific Policy and the Growth of the British Economy"\* which Mr. C. F. Carter and Prof. B. R. Williams contributed to the September 1964 issue of *The Manchester School*, makes pertinent reading now that the shape of the Government's organization and plans for civil science and for technological and economic development are beginning to appear. It may well be some time before lines of scientific policy are definitely laid down by the Government, but meanwhile this paper takes the more general discussion which was stimulated by Dr. S. Toulmin in his paper in 1963 on the foundations of scientific policy a stage further, and into a specific British context. (Dr. Toulmin continued his theme in a talk, "Science and the State", broadcast on the B.B.C. Third Network and printed in *The Listener* for June 11, 1964, as well as in an article in *Minerva* last spring, entitled "The Complexity of Scientific Choice".) Pertinent to the discussion also are such papers as Mr. J. Maddox's "Choice and the Scientific Community" (*Minerva*, Winter 1964) and those contributed to *Scientists and National Policy-making*, edited by Prof. R. Gilpin and Dr. C. Wright (see p. 428 of this issue of *Nature*). Nor should it be overlooked that, besides Sir William Slater's discussion, in the Joule Memorial Lecture, of Government as the patron of science, Lord Todd, in the Dalton Lecture of the Royal Institute of Chemistry, also in October, considered the relations between Government and technology, and Prof. R. H. Kantorowich, again in Manchester, called for a national strategy of land use and settlement as an essential counterpart of defence policy or economic policy.

From varied and independent sources there is thus being gathered much authoritative material for the formulation of scientific policy, as well as for its assessment. Mr. Carter and Prof. Williams begin by pointing out that a country's eminence in science is not a good guide to its economic strength and growth, nor indeed something to be measured with precision. Current economic growth depends much more on success in applying existing science and technology than on current rates of expenditure on research and development: the stock of knowledge rather than the flow of new knowledge is the important factor, and the relations between science and growth are too complex to be derived from national expenditure on research and development.

Accordingly, Prof. Williams and Mr. Carter begin by showing how the use of scientists and engineers—the supply of whom depends on education—in the interests of economic growth raises questions about their distribution in different but related activities such as research, development, production, technical sales or management—even in education. However, they do not raise as specifically as did Sir Richard Clarke in his Stamp Memorial Lecture the question of whether or not Britain could afford to employ in teaching some 350,000 out of 750,000 persons in Britain with a full-time higher education.

The appropriate way of using scientists will depend on the relative costs of developing one's own innovations or

buying them on licence from abroad, and on the related cost of using scientists in research instead of in production. Growth can be impeded if, as in Britain, too high a proportion of scientific manpower is engaged in adding to the stock of knowledge and too small a percentage in using it. This point is seldom considered in discussions on industrial research and development or the balance of the research effort. However, its importance can be at least as great as the efficiency with which research or development is conducted, and the soundness of the judgment with which projects are selected or managed. The same factor may also influence the effectiveness of communication between experts in research and development in production, finance and marketing: unbalanced distribution in one sector reacts on the effectiveness of work elsewhere. The paper emphasizes especially the importance not merely of a wise distribution of Britain's limited scientific manpower but also the importance that decisions about its distribution should not be made piecemeal or sectionally but from a balanced view of the whole situation. This is, indeed, the fundamental purpose of Government policy and action, but it is one which since the War no Government seems to have possessed the wisdom or courage to pursue. Yielding to sectional interests has usually destroyed any semblance of a national and balanced policy.

Few would now dispute Prof. Williams and Mr. Carter's argument that the question is no longer whether Government should take action but rather the extent of such action. Directly, they maintain that the Government must provide for the education of a sufficient number of scientists, technologists and supporting technicians, and for certain scientific information services, such as major libraries. It must also accept responsibility for scientific research and for certain applied research for which the Government is the major customer. There are other spheres where Government action is more prudently exercised indirectly, and it is the selection of the points of intervention that tests the soundness of judgment and policy. To apply effort at points where little result can be achieved is a waste of effort, however satisfying to some political dogma. There is no substitute for clear thinking, and the wise maker of policy uses many instruments and none to excess.

Most of the instruments listed by Mr. Carter and Prof. Williams have already been mentioned in Parliamentary debates in the present session. There is direct control of production, of which they observe that unitary control may sometimes lead to a centralization of research policy, so nothing is done which does not fit the ideas of one man or a small group. Of encouraging production by subsidy or large initial orders by the Government, they note that, where the Government is an important buyer, its buying power can be used relatively easily to encourage applications of science. Control of developments by direct Government contracts can promote desirable changes in organization as well as specified developments, but the use of tax incentives may present difficult problems. Again, they point out that although direct Government action in applied research through research stations solves the problem of getting research done for an industry unwilling or unable to conduct such research itself, the

\* "Government Scientific Policy and the Growth of the British Economy". (Reprinted from *The Manchester School of Economic and Social Studies*.) By C. F. Carter and Prof. B. R. Williams. Pp. 20. (Manchester: *The Manchester School*, Department of Economics, The University, 1964.)

problem of applying the results remains. Moreover, even though it is supporting research which industry would undertake to do itself, the Government, by making tax concessions, specific research grants or grants to research associations, etc., increases the probability that the results will be applied. However, the influence on what research is carried out is less, and it is not easy to influence a research association which chooses to ignore the chance of a major change in technology and concentrates on minor refinements of instrumentation. Finally, they refer to the way in which Government action can encourage the employment of scientists and technologists, notably by increasing the supply as well as improving the use made of them by increasing the supply of technicians.

On this last-mentioned point it is surprising, in such a forthright paper, to find no condemnation of the hoarding of manpower. Particularly in the context of Government proposals for dealing with redundancy this is probably one of the most serious dangers threatening the British economy. The problem of scientific policy, it is rightly urged, is not one of devising totally new methods, but of applying more forcefully, and in new areas, methods which have long been used or considered. Along with this more forceful application must go the recognition that there is no general answer to the problem and that to make a measure with the appropriate degree of force in particular circumstances is going to hurt some groups or interests much more than others. Failure to be sufficiently ruthless and mistaken attempts to treat everyone alike are responsible for much that is amiss in industry to-day.

Accordingly, Mr. Carter and Prof. Williams suggest that a Government requires many means of intervention as well as some method of assessing what should be done in different parts of the economy and of repeating such assessments from time to time competently and rapidly. For this purpose they lean towards the idea of a small research team of scientists and men with business or economic training, advised by knowledgeable assessors. Any such team should be attached to a Ministry in day-to-day touch with the relevant sector of the economy and responsible for Government policy towards that sector. It follows that little value is attached, on this view, to independent assessment, but at the same time it is recognized that Government departments generally are nowadays rarely staffed with specialists of the type required. Creation of strong research divisions (composed of small project units) is recommended in each department which has direct responsibilities for relations with industry, commerce and services, even if some changes are in consequence necessary in the structure of the Civil Service. Similarly, relating applied research and development as closely as possible to Ministries responsible for production is advocated in the paper, and Mr. Carter and Prof. Williams do not agree that the applied research of the Research Councils should fall under a separate Ministry for Science, even if this necessitates drawing another line between pure research and higher education. In this context they make a wise comment as to the value of alternative sources of finance to the University Grants Committee as a guarantee of freedom in research—a factor which has received little recognition in comments either on the Government's present proposals or on those of the Trend Report.

This line of thought leads to a recommendation to transfer to a reconstructed National Research Development Corporation, with new terms of reference, that aspect

of the work of the Department of Scientific and Industrial Research concerned with awarding development contracts and grants to applied research; meanwhile the work of its Industrial Grants Committee would go to the Board of Trade, which would be assisted by an outside advisory committee. They would place the Road Research Laboratory in the Ministry of Transport, the Building Research Station in the Ministry of Public Buildings and Works, and other research stations would be treated similarly where a clear functional responsibility could be seen—the Agricultural Research Council going to the Ministry of Agriculture, Fisheries and Food. Such proposals, however, might well be subject to second thoughts in the light of some comments which Dr. S. Toulmin makes about United States experience. Responsibility for postgraduate training awards would be transferred to the Ministry of Higher Education, while research grants in pure science would become the responsibility of a Science Research Council, which would also be responsible for the National Physical Laboratory, and with research stations. This structure would be flanked by the Medical Research Council, the Nature Conservancy, and new Councils for Social Science and the Humanities, all of which would be responsible to the Lord President of the Council.

Clearly this is considerably different in various respects from the structure recommended by the Trend Committee or that which the Government is now establishing. It possesses, moreover, some significant defects, even where superficially most attractive. The proposal to locate research stations within the Department ignores the value which is sometimes attached, as with the Building Research Station, to independence in advice, nor has account been taken of considerable practical difficulties which would arise in determining alignment. Again, although there is a welcome recognition of the importance of information services and a survey of such services to determine whether the most effective work is based on provision by industry or locality, the proposal to distribute among the production departments the information functions of the Department of Scientific and Industrial Research is highly dubious and more likely to hinder than to promote the development of the national library and information services which Britain needs.

So far as the instruments for the formulation or execution of scientific policy are concerned, the proposals by Mr. Carter and Prof. Williams are debatable; however, they are to be welcomed for the emphasis which they put on needs which must be served, some of which the Government's present proposals tend to ignore. As regards actual policy, they give a high priority to improvements in educational selection and measures to counteract social influences which lead to waste of ability, as well as to the more sensible use of scarce manpower. There is a timely reminder that Britain's resources are limited. We cannot possibly lead in every area of pure science and technology, and it is urged that we might benefit by transferring resources from science to industrial technology, and that we might participate more fully in international trade in technical knowledge. Wisely, too, it is urged that large new commitments involving scarce manpower should be viewed with great suspicion, and once again a high place is given to the extension of information and advisory services and the general increase of scientific and technical literacy in the nation.

One blemish unworthy of a stimulating and suggestive paper is sour and unjustified comment on the Advisory

Council of Scientific Policy, which has consistently sought to prevent dissipation of scarce resources in such fields as space research and whose policy of filling in gaps (which has been pursued realistically) is far from being nonsensical as is here suggested. That apart, it is reasonable to suggest that first priority in the use of scarce resources should go to strengthening those few industries in which Britain already has a technical lead which could be maintained or increased. Next, the Government should direct attention to those activities in which at small extra effort, perhaps by purchase of technique, Britain could do at least as well as her commercial rivals. Massive concentration of effort on the revival of seriously backward sections is dubious and perhaps to be avoided. Here perhaps, above all, may come the call for resolution and a certain ruthlessness which, at least as much as good advice and appropriate organization, are what Britain needs for the health of her economy.

Some of these points were emphasized by Prof. B. R. Williams in his presidential address to Section F (Economics) at the meeting of the British Association for the Advancement of Science in August last. Speaking on "Economics in Unwanted Places", he pleaded that cost-benefit analysis should be used to guide Government expenditure on research and development, referring particularly to the second nuclear power programme and the aircraft industry, and to the desirability of judging investment in scientific research in the light of the probable social benefits. Even before the election it seemed fairly clear that whatever Party was returned to power the new Government would have to devise some new and more satisfactory system for the formulation of scientific policy; it is worth noting that in a further paper at the Southampton meeting of the British Association, presented before Section N (Sociology), Mr. D. S. Pugh and Mr. C. R. Hinings, of the Industrial Administration Research Unit at the Birmingham College of Advanced Technology, described some results in an empirical examination of bureaucracy in the management of some fifty organizations in the Birmingham area. The relevancy of such an examination is well brought out by Prof. C. Frankel's article, "Bureaucracy and Democracy in the New Europe", in the Winter 1964 issue of *Daedalus*.

Such investigations are, in fact, vital when the forms of Government organization are being transformed. Prof. Frankel points out that the problems of bureaucracy and of the relation of specialists are all too frequently ignored, and of the major social philosophies of the nineteenth century only Comte and Tocqueville gave the problem systematic attention. Reconciliation of a conception of popular Government based on models drawn from small communities, with the imperatives of Government in large nation States, is not easy, and even in present discussions of the reform of Parliament the issues are sometimes overlooked. Prof. Frankel's realistic discussion displays the real issues: the working touchstone of a democratic system of authority is simply the degree to which it gives individuals legitimate instruments for reaching those who made the decisions that affect them, and for bringing influence to bear on them. That applies where science and technology are concerned just as in other fields, and here too it is imperative that besides the electoral system itself there must be independent resources such as newspapers and periodicals, professional or learned associations, which allow professional men to make their views known and exert effective pressure on their leaders.

Prof. Frankel refutes the idea that bureaucracy is incompatible with this conception of democracy, which accepts the necessity for central leadership; at the same time he shows that political leaders to-day cannot discharge their tasks competently and intelligently without the advice and assistance of a large corps of specialists whose office is not dependent on election and whose loyalties are given equally to any Government. There are important considerations in judging the appropriateness of new institutions, and Prof. Frankel points out that an independent judiciary, free institutions of enquiry and education and private associations all create a vested interest in maintaining constitutional guarantees of liberty, nor has the loss of initiative by Parliament diminished its function of airing grievances. If the importance of personal rights as opposed to administrative authority has yet to be fully recognized the problem is already receiving some imaginative attention.

Beyond this, Prof. Frankel makes some suggestive points about the desirability of new political associations in the light of the new forces of science and technology, productivity and efficiency. It is a major function of the democratic method to prevent decisions being taken that are based on narrow definitions which leave out vital aspects of the interests and issues at stake. Bureaucratic decision-making has to be brought into the open where it can be surveyed and controlled, and those who exercise bureaucratic power placed under pressure from visible and significant competitors. Changes in a democratic system should be such as to encourage such democratic participation and foster the use of all the interest and experience such a society can provide. Conceived on such lines, planning, while providing a framework in which individuals can make their choice, does not necessarily increase the specific interventions by the State, while it can make the citizen aware of larger social purposes in everyday life and supply a sense of meaning and direction.

These criteria for assessing the appropriateness of the Government arrangements for civil science indicate that professional organizations have an important, indeed an essential, part to play, and the lead recently given by the Royal Society should be widely followed. On the content of policy itself, the complexity of the problem implies flexibility and renders almost inevitable a wide divergence of opinion. The pragmatic approach of Prof. Williams and Mr. Carter is almost diametrically opposed by Prof. M. Polanyi's, as Dr. Toulmin points out in the attempt to find common ground which he contributed to the Spring 1964 issue of *Minerva* under the title "The Complexity of Scientific Choice: a Stocktaking". Nor is this any condemnation of the scientist or such a body as the Advisory Council on Scientific Policy. Perhaps the most important passage in Dr. Toulmin's article is that in which he emphasizes that the cardinal choices in national policy are necessarily political choices, to be made at Cabinet level; by the time they reach that status the points of decision will have had to be restated, so ceasing to be technical questions about scientific importance, and becoming political questions about the rival claims of health, defence, higher education and the rest. Unless this central principle is firmly grasped, neither the content of scientific policy nor the arrangements for its formulation and execution can be fairly assessed—not that Dr. Toulmin is entirely satisfied with the arrangements which existed when he wrote. Some of his criticisms have been met by subsequent changes, but his point about the real cause of any weakness in the Advisory

Council on Scientific Policy still stands. In his view that Council should be responsible not to the Lord President of the Council in his role as Minister for Science but to the Cabinet. That the point had been taken might follow from certain tentative arrangements which the Prime Minister has already made for strengthening the Cabinet Office. Meanwhile, it is to be hoped that both inside and outside the Government new arrangements will be impartially assessed in the light of the momentous value of informed criticism.

## ORGANIZATION OF SCIENTIFIC ADVICE

Scientists and National Policy-making

Edited by Robert Gilpin and Christopher Wright. Pp. viii + 307. (New York and London: Columbia University Press, 1964.) 7.50 dollars.

A PART from a review by Sir Solly Zuckerman and comment by Dr. S. Toulmin in *Minerva* on taking stock of the complexity of scientific choice, this collection of essays has attracted little attention in Britain, in spite of the stimulus to thinking about scientific policy given by the international ministerial meeting on science at the Paris headquarters of the Organization for Economic Co-operation and Development in October 1963. Nevertheless, although primarily concerned with the making of policy in the United States, most of the essays are of even greater interest in the light of the new measures which the present Government has taken for the organization of civil science in Britain and to associate scientists with the formulation of policy. Whatever basis there may be for the suggestion that the new arrangements follow the Presidential structure, these essays are, as Dr. Toulmin points out, a most useful contribution to the discussion of the general problem and to assessing the soundness of particular proposals.

A few of the essays have already been published. These include D. K. Price's discussion of the nature and role of the scientific establishment in the United States; Prof. W. S. Sayres's "Scientists and American Science Policy"; and Prof. W. R. Schilling's "Scientists, Foreign Policy and Politics". Apart, however, from R. N. Kreidler, who writes on "The President's Science Advisers and National Science Policy", and H. Brooks, who deals with the Scientific Adviser, it is not made clear how far the authors are themselves writing from inside knowledge and association with the task of formulating policy and not simply from academic studies. Of the remaining essays, Prof. R. C. Wood contributes one on "Scientists and Politics: the Rise of an Apolitical Elite"; Prof. A. Wohlstetter writes on "Strategy and the Natural Scientists" and B. Brodie discusses "The Scientific Strategists". Dr. C. Wright's "Scientists and the Establishment of Science Affairs", which concludes the book, makes an appropriate counterpart to the admirable introductory essay by his co-editor, Prof. R. Gilpin, "Natural Scientists in Policy-making".

The essays thus range widely, though the common theme is clear and strong. Likewise, much of the stimulus is derived from Sir Charles Snow's Godkin Lectures in 1960, and it differs from some other American books in that the British contribution to the debate is reasonably reflected. Mr. Gilpin's introduction brings out very clearly the way in which the participation of scientists in the formulation of policy in the United States has developed in the past quarter of a century and the character of their contribution in relation to national support for science and to national security. These questions are explored more fully in the subsequent essays, but it is chiefly in those by Brodie and Wright,

which discuss the possibility that new types of expertise must be developed to cope satisfactorily with the problems now created by the interactions of science, technology and society, that any essentially fresh contribution is made. By and large, the value of the symposium lies in presenting in reasonable compass the position of present-day developments in this field in the United States and the trend of an important section of informed opinion.

Nevertheless, certain important points clearly emerge. If the crucial nature of the scientific contribution to national strength is manifest, too much is never claimed. Scientists in Government do not suggest that their advice should be overriding, but they do insist on the value and importance of scientific advice in reaching a balanced decision where scientific issues are involved. This is not simply a matter of the arrangements for tendering scientific advice or the calibre of the adviser: it is a matter also of public understanding, and herein lies the value of Christopher Wright's analysis of the bridges which in recent years have been built between science and society. The implications of this essay deserve pondering, not simply by scientists or technologists as individuals but also by their professional associations. There is wide scope for creative thinking on this point to which the social scientist, as well as the physical scientist and the politician, has his own contribution to make. Moreover, as Harvey Brooks points out, the magnitude of scientific and technological enterprise to-day and the influence which the scientific adviser already exerts on public policy expose the scientist to criticism which could be dangerous to science itself in the absence of public understanding. Scientists can no more afford to neglect to make the organization for advice as effective and efficient as possible than they can to promote public understanding of the nature and limits of science. Nor are scientists likely to tender usable advice without some understanding of the nature and limitations of politics.

It is thus mainly for its constructive approach to the problems of the organization of scientific advice that the book is important. It does not ignore the question of the content of scientific policy: the form of organization most appropriate can scarcely be determined without reference to that content, to the purposes to be served. Although such reference, even in Christopher Wright's essay, is slender, it has wide implications for the scientist and is perhaps one of the most constructive features of a timely and stimulating book.

## SCOTLAND'S GREEN MANTLE

The Vegetation of Scotland

Edited by Dr. John H. Burnett. Pp. xiii + 613 + 96 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1964.) 126s.

THIS is an account of Scottish plant life in its environment, written by the members of a group of ecologists and edited by Prof. J. H. Burnett, formerly of the University of St. Andrews and now of the University of Newcastle upon Tyne. Prof. Burnett contributes the introductory chapter, in which the history of plant ecology in Scotland is reviewed. The Perthshire brothers Robert and W. G. Smith, in the years immediately following 1898, laid the foundations of the study in Britain; the premature death of Robert, and his brother's move to Leeds, directed the focus of activity south of the border, where its first major fruit was A. G. Tansley's *Types of British Vegetation* (1911). In Scotland, Robert Smith's immediate successors soon disappeared from the scene and the early momentum was lost; the next thirty-five years produced only isolated papers of consequence on Scottish vegetation. Just after the Second World War the work of Gimingham, McVean, Poore and Ratcliffe stimulated a Scottish revival.

Poore adapted the technique of 'successive approximations', favoured by prominent continental ecologists, to the investigation of Scottish hill plant communities, and the method proved so successful that it has been applied to most of the vegetation zones examined in the present work. As a result, the basic vegetational units are smaller, more natural and more precise than those used by Tansley in his later work, *The British Islands and their Vegetation* (1949).

The remainder of the text is in three sections: two chapters on physical background (climate and soil), followed by twelve on vegetation and a final two on history and pattern. The plant nomenclature adopted is the most recent available: Clapham, Tutin and Warburg's *Flora of the British Isles* (1962) for flowering plants and ferns, and for the other cryptogams the present census catalogues.

The account of climate, given by F. H. W. Green of the Nature Conservancy's Speyside Research Station, is an analysis of Scottish weather as it affects plant life. The evolution of Scottish soils from pre-glacial times and the characteristics of more than thirty types of modern soil are dealt with in the chapter on soil—the work of Dr. E. A. Fitzpatrick. These two chapters on the physical background cover between them some 50 pages; the middle section, on vegetation, takes almost 500. The order of treatment here is altitudinal, from the sea's edge to mountain summits. The chapter on the maritime zone is the work of Dr. C. H. Gimingham, of the Botany Department in the University of Aberdeen. The great length of coastline bounding the Scottish mainland and islands, and the diversity of its scenery, result in a wide variety of habitats; the plant communities of cliff faces, rock ledges, shingle, saltmarsh, dune country and machair all come under review.

Three chapters are devoted to the forest zone. One, on woodland and scrub, written by Dr. D. N. McVean, formerly of the Nature Conservancy's Speyside Research Station, recounts the chequered history of Scottish woodlands; a history complicated by introductions as well as by felling, burning and grazing, so that distinguishing the native from the planted is not always easy. Two members of the staff of the Hill Farming Research Organization, Dr. J. M. King and Mr. I. A. Nicholson, contribute a chapter on low-level grasslands. The fluctuating fortunes of the woodlands are reflected in the history of grassland communities; as the authors point out, Scotland's economic history over the past 200 years has been closely linked with the evolution of her grasslands, in which the main factor has been biotic. Dr. Gimingham's chapter on dwarf shrub heaths concludes the account of the forest zone; this type of country has long been the author's special study, and here he is very much on his native heath. He concludes with an account of economic heathland management, involving controlled burning, and traces the stages in recovery.

Another three chapters are taken up with the lowland aquatic zone. The first, on phytoplankton in Scottish lochs, is written by Dr. A. J. Brook, of the Botany Department in the University of Edinburgh. Relatively little work has been done on this subject since the original investigations by the brothers West fifty years ago; indeed, the author of the chapter is personally involved in about half the small number of papers quoted in reference. On the other hand, the chapter on the macrophytic vegetation of these habitats by Dr. D. H. N. Spence, lately of the Botany Department in the University of St. Andrews, is the longest in the book, and the length of the reference list indicates that this is a topic which many workers have found attractive. Dr. D. A. Ratcliffe, now at the Conservancy's Experimental Station in Monk's Wood, concludes the account of this zone in a chapter on "Wetlands" (mires and bogs); the term 'mire' is equated to 'soligenous bog'. The author estimates that, while about one-tenth of Scotland's total land-surface is at present bogland, the

rapidly growing demands of agriculture and afforestation will drastically reduce this fraction.

The final section in this part of the volume consists of five chapters devoted to the montane zone; all but the last of these are by Dr. McVean. No altitudinal limits are specified for this zone, but it is apparent from the text that it extends upwards from about 1,000 ft., and that all the communities here described can be found in the 2,000–3,500 ft. range. Some of the associations already described in the lowland zones have their parallels here: thus Chapters 11 ("Dwarf Shrub Heaths"), 12 ("Grass Heaths") and 15 ("Montane Mires")—the last-mentioned by Dr. D. A. Ratcliffe—are all projections to higher altitudes of the comparable habitats in the lowland zone. Here changed conditions of altitude, slope and aspect have so modified the climatic and biotic factors as to alter the composition of the plant communities. Two new types of association are recognized in this zone; these are herb and fern meadows (Chapter 13) and moss heaths (Chapter 14). The latter, which do not occur below 2,000 ft., and are beginning to be significant at 2,500 ft., are the associations occupying the highest levels.

Dr. McVean is the author of both chapters in the short third and final section of the volume; they deal with history and pattern. In the first of them the theory of a post-glacial origin for the flora is accepted, and the changes wrought by 15,000 years of climatic fluctuation, as evidenced by plant remains and pollen deposits in peat, are outlined. The final chapter is on regional pattern; in it the author postulates that vegetation regions do exist in Scotland, and makes an arbitrary division of the mainland into four of these. Cultivated land is excluded, and the islands are treated separately—not from natural causes, but for reasons of convenience; in fact their vegetational affinities lie with the adjacent mainland regions.

The text is followed by four indexes, occupying some 35 pages; one is general and the others list the names of authors, places and plants. In the list of authors the name of the late W. H. Pearsall has a prominent place; he would have delighted in this work, of which his own *Mountains and Moorlands* was a natural precursor. References to literature occur at the end of each chapter; the book would be valuable to students for these classified lists alone. There are close on a hundred photographic illustrations; three of these, depicting the horizons identifiable in characteristic Scottish soils, are in colour. Many of the others are full-page; most of these are very good and some are excellent. Dr. Berry's photograph of Rassal ashwood is one of the finest in the book, but others in the same and later chapters also convey the atmosphere of the habitat very successfully. Presumably considerations of space dictated the reproduction of two or even three photographs to the page in other cases; these are mainly of good quality, but for some a larger scale would have been an advantage. Of particular interest is a series of illustrations of fresh-water habitats, for comparison with others taken at the same sites by George West, more than half a century earlier. There are more than 60 maps and line diagrams of various kinds, and 65 tables analysing the vegetation in the various communities.

There seem to be few misprints; some occur in footnotes (pp. 169, 222, 292) and are not misleading. There is an obvious misnomer in the caption to Plate 90, where *sanguineum* should be *sylvaticum*, and two page-headings (pp. 496, 497) are misplaced. The accuracy of the tabulated data must be assumed.

In a volume which contains so much of absorbing interest, one must guard against being over-critical on minor omissions. I felt that there might have been room for some discussion of the effect on pasturage of the Highland clearances during the first half of the nineteenth century, with the consequent replacement of cattle by sheep; nor does there seem to be any reference to records made in the Hebrides, from 1934 onwards, by exploring

parties from the Botany Department in the University of Durham. On points of detail, the application of the name *Juncus fluitans* to the fluitant state of *J. bulbosus* may be unfamiliar to some readers; the term is at present out of favour with systematists, and is not quoted in modern Floras. The list of species given for the tall herb association of flushed ledges in the montane zone seems unduly restricted; in this habitat one is accustomed to meet *Anemone nemorosa*, *Silene dioica*, *Filipendula ulmaria*, *Rumex acetosa*, *Oxyria digyna*, *Carex binervis* and some species of *Dryopteris* as frequently as other plants included in Table 61; again, it is surprising to note the absence of *Carex lepidocarpa* from low-level basic flushes (Table 64).

This is not a book for the pocket; it weighs almost 4 lb., and is built in proportion. Nor, despite its size, would its authors claim any finality for it; the editor himself points out the poverty of published work on the vegetation of montane lochs and of the islands. Scotland's lochs remain "relatively unstudied", and the analytical study of its "vast acreage of bogs and mires" has scarcely begun. Indeed, the author of the longest (and one of the best documented) chapters admits that "the total number of localities (fresh-water lochs) studied throughout Scotland barely exceeds the number of such habitats in Galloway alone; the Outer Hebrides... were omitted, and the larger Highland lochs are under-represented". For all five chapters on the montane zone, as for that on phytoplankton, the reference lists are pathetically short; indeed, the pointers to the future are implicit in most chapters. Yet the publication of this work is a major event in British botany, and one which must bring great satisfaction to its authors; the laborious years of preparation are over, and they have produced a volume which, for years to come, will be invaluable both as a reservoir of existing knowledge and as a stimulus to future workers. Nothing like it exists for any other part of Britain, but it is surely appropriate that the country in which the Smith brothers began, almost seventy years ago, the investigation of British plant ecology should now be the first in these Islands to produce so detailed an account of its vegetation. Its appearance will be hailed with satisfaction overseas as well as at home—a satisfaction tinged, perhaps, with regret that its production could not have been timed for a year earlier; there would have been no better briefing for visitors to the Edinburgh Congress in August 1964 than a few months with this fascinating book.

R. MACKECHNIE

## ORAL BIOLOGY

### Advances in Oral Biology

Vol. 1. Edited by Peter H. Staple. Pp. xiii + 353. (New York and London: Academic Press, 1964.) 100s.

THIS is the first of a projected series of volumes designed to present to research workers in oral biology and related fields critical review articles of recent work. It is hoped in this way, as the editor informs us in his preface, to facilitate the dissemination of information among the small, and geographically widely separated, groups who are interested in oral health and disease.

The present volume contains articles by workers whose names will be familiar to those who are interested in research in the oral field. These articles range over a wide area and give exhaustive and authoritative surveys of the subjects under discussion, with illustrations and bibliography. Some of the topics are likely to appeal to a relatively restricted readership, though others will attract a wider audience. In the former category is Mühlemann and Schroeder's paper on the dynamics of supragingival calculus formation. This is a review of recent research on the structure and variations in rate of formation of dental

calculus (tartar), including techniques for qualitative and quantitative estimation. In this class also are Walsh's review of the relationships of surface active agents, the enamel surface and dental caries, Carlström's account of the polarization microscopy of dental enamel and the incipient lesion of dental caries, and Armstrong's paper on the modifications of the properties and composition of the dentine matrix caused by dental caries. But even in these accounts, highly specialized though they may be, there are aspects that will be of interest to workers in fields apparently quite unconnected with oral pathology and dental disease. This is certainly the case in most of the remaining reviews; they will undoubtedly be of interest and value to biochemists and others concerned with bone growth. Among these reviews may be mentioned Hartles's paper on citrate in mineralized tissues, which gives a valuable résumé of the work done on this subject in the past twenty years—since, in fact, the discovery that citrate is present in bone in appreciable amounts. Bevelander reviews the effect of tetracycline on mineralization and growth—again a useful summary for those who use this technique for bone growth investigations. Morphologists will also be interested in Ness's account of movement and forces in tooth eruption, a very fully documented review of recent observational and experimental work on rodents and man.

The remaining articles, on the secretion of saliva by Schneyer and Schneyer, the physiology of mastication by Kawamura, cytochemical aspects of oxidative enzyme metabolism in the gingivae by Eichel and Shahrik and a review of recent investigations of mucins and blood group substances by Pigman and Hashimoto, will also be of considerable interest to research workers in the oral field and to those with related interests.

The editor of this volume hopes that the series will help many workers in the basic sciences to see that the investigation of oral biology in relation to oral health and disease offers great opportunities for fundamental investigations in their own disciplines. If succeeding volumes maintain the standards set by this one, the editor's hopes deserve to be fulfilled.

R. B. LUCAS

## ANALYTICAL METHODS FOR INSECTICIDES

### Analytical Methods for Pesticides, Plant Growth Regulators, and Food Additives

Vol. 2: Insecticides. Edited by Gunter Zweig. Pp. xvii + 691. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 164s.

WHILE a putative purchaser might have felt some doubts as to whether the first volume of this treatise, entitled *Principles, Methods and General Applications*, was worth buying, he need have no hesitation about Volume 2. Anyone concerned with the analysis of modern insecticides will need it as an essential tool.

The book is a model of its kind. Each of its forty-seven chapters deals with a separate insecticide. Chapter 1 about aldrin is followed in alphabetical order by the next about allethrin and so on to aramite, baytex and chlordane. Then, after dylox, guthion and heptachlor; rhotane and ronnel; sevin, systox and tedion; thiodan, toxaphene and trithion, there come, in Chapters 46 and 47, vapona and zectran. The system followed in each chapter is the same. The chemical formula of the active substance and its systematic name are followed by the empirical formula, the alternative trivial or trade names—for example, DDT, it seems, may also be called 'Dicophane', 'Gesapol', 'Gesapon', or 'Neocid'—the source from which a standard sample of the material can be obtained, a sentence or two about its biological properties and reference to the first publications in which it was described. Next come

details of its physical properties, the method by which it is synthesized where this is available, its main chemical reactions, and the types of formulations in which it is most commonly marketed.

The main part of each chapter and the essential core of the book, however, are the clear and explicit descriptions of analytical methods, first for formulations of the insecticides and then for crops or animal tissues likely to contain residual quantities of them. The principles of the available analytical methods are first outlined and references given to alternative procedures. Recommended methods are then described in full detail.

The advance of scientific understanding to-day redounds to the glory of the human intellect. Scientific theory, however, is based on accurate observation and observation depends on technique. This is a book on technique. For example, to determine traces of tedion (2,4,5,4'-tetrachlorodiphenyl sulphone) in fruit, it can be nitrated and treated with alkali in the presence of pyridine to give a red colour. It is, however, useful to be told that uniform nitration cannot be achieved without the addition of a 'keeper' and that the best 'keeper' for tedion is lanolin. The book is full of such useful detail; in some cases drawings of apparatus are included as well as precise working instructions. Sometimes, the very virtue of the full and painstaking precision with which methods are described may present problems for the analyst who lives on the right bank of the Atlantic. It may not be convenient for a British chemist to obtain premixed reagent for aldrin analysis from Austin, Texas, or adsorbent "attaclay" from Menlo Park, California.

The new synthetic insecticides with which this book deals are not only a striking example of the great advances that have taken place during the past few years in general toxicology, insect biochemistry, plant physiology and organic chemistry. As we know all too well, their advent has demonstrated how subtly progress in one facet of biology can disturb the delicate balance of Nature. This admirable compilation of analytical methods is an example of the painstaking laboratory work on which all our efforts to achieve a rational solution of the different problems raised by these new discoveries ultimately depend.

MAGNUS PYKE

## EXPLOSIVES, CHEMISTRY AND TECHNOLOGY

### Chemistry and Technology of Explosives

Vol. 1. By Prof. T. Urbanski. Translated by Irena Jeczalikowa and Sylvia Laverton. Pp. xv + 635. (London and New York: Pergamon Press, 1964.) 140s.

THIS volume is the first of a series of three volumes covering the chemistry and technology of explosives. The original Polish edition of this book was published in 1953-54 and was followed by Czech and German editions. The present fourth edition, translated from the Polish, is a considerably revised and expanded version of the earlier ones.

Since the classic four-volume treatise on explosives by Marshall (1917) a number of books have been published on the subject, to cover the expanding knowledge in the field. Some of these deal more with the physics of explosion/detonation processes, while others emphasize the technology of manufacture and applications. There has, however, been no publication covering the chemistry of explosive compounds, their physical and physico-chemical properties and details of manufacturing processes, in a wide perspective, suitable for explosive chemists and research workers. The present book adequately fills this gap.

The scope of the present volume is indicated by the following chapter headings: 'Nitration and Nitrating

Agents'; 'Nitration Theories'; 'Nitration Agents and Methods More Rarely Used'; 'Nitration with Nitrating Mixtures'; 'General Information on Nitrocompounds'; 'Aromatic Nitrocompounds'; 'Nitro Derivatives of Benzene'; 'Nitro Derivatives of Toluene'; 'TNT Manufacture'; 'Nitro Derivatives of Higher Benzene Homologues'; 'Nitro Derivatives of Naphthalene'; 'Nitro Derivatives of Halogeno Benzenes'; 'Nitro Derivatives of Phenol'; 'Manufacture of Picric Acid'; 'Other Nitro Derivatives of Phenols'; 'Picric Acid Ethers'; 'Nitroderivatives of Aniline'; 'Nitro Derivatives of Azo and Hydraso Benzenes'; 'Aliphatic Nitro Compounds'; and 'Nitronitroso and Nitroso Compounds'.

All the foregoing chapters are not merely descriptive but provide copious experimental data in the form of figures and tables, illustrating the theoretical concepts, chemical reactions and technical processes. The treatment of the subject is thorough in all the chapters, for example, the chapter on 'Nitro Derivatives of Toluene' details general information on toluene nitration with mixed acid, such as extent of nitration with different compositions of mixed acid, change of nitration rate with temperature; physical, chemical and thermochemical properties, toxicity, laboratory and industrial methods of preparation and separation of isomers and mono-, di- and tri-nitrotoluenes; effect of heat and light on  $\alpha$  TNT, reactions of  $\alpha$  TNT with various chemical agents, addition products, elucidation of constitution, kinetics of nitration of DNT to  $\alpha$  TNT both in homogeneous and heterogeneous systems; explosive properties of TNT; unsymmetrical isomers of TNT, their physical and thermochemical properties and chemical reactions with various agents; other by-products of toluene nitration, and tetranitrotoluene.

All chapters are provided with literature references at the end, covering publications up to 1960. One must not expect the same up-to-dateness in a comprehensive treatise like this as in a newspaper, and the author is to be commended for the literature coverage presented. An author index and subject index are also provided at the end.

The book is a mine of information for the explosive chemist. Not only is it a collected source of published information on what has been done but it is also a fertile source of new ideas to a discerning reader. To many the enormous amount of work reported from East European countries will become available for the first time. Details of a number of German and Japanese processes of explosives manufacture, disclosed at the end of the Second World War, in the CIOS, BIOS and FIAT publications, have also been included.

There are some very minor omissions; for example, there is no mention of the "white compound" formed in the continuous TNT manufacture. Its constitution and that of its degradation products have consequently not found a place in the nitro derivatives of azoxy compounds. Similarly, work on action of light on TNT, formation of 2-nitroso-4:6-dinitro-benzoic acid, the precursor of "white compound" and the possible relation of the "white compound" to the early products of photodecomposition of TNT (*Chem. Abstr.*, 48, 13656 a; 1954), has also escaped notice. It has also been overlooked that the formation of a eutectic of tetryl with  $\alpha$  TNT (p. 295) has been questioned (*Chem. Abstr.*, 40, 209; 1946).

The book is well produced and the translators have done a fine job. There are a few misprints (for example, reaction 11, p. 57; reaction C" on p. 63; ref. to p. 274 for p. 271 on p. 65), but these are not likely to cause confusion.

This is an excellent volume and can be wholeheartedly recommended for students and research workers in both explosives and organic chemistry.

W. D. PATWARDHAN

# FISSION PRODUCT FALL-OUT FROM THE NUCLEAR EXPLOSIONS OF 1961 AND 1962

By D. H. PEIRSON and R. S. CAMBRAY

Atomic Energy Research Establishment, Harwell, Berks

THE massive programme of nuclear weapon testing during 1961–62 started three years after the previous substantial series of explosions in 1958. In the 16-month period of testing 1961–62 the amount of fission reported<sup>1</sup> was roughly equivalent to that during 1952–58, but obviously at an increased rate. In addition to an increased rate of fission production in 1961–62 there were fewer high-yield explosions at or near ground-level, thereby reducing the proportion of fission products injected directly into the troposphere, and some individual explosions were very large, implying insertion to higher altitudes. It is to be expected that, compared with the earlier period, debris from the more recent series of nuclear tests would reside in greater proportion in the upper atmosphere and, on return to Earth, would thus contain a smaller proportion of short-lived fission products.

This article, based on fission product measurements already reported<sup>2–4</sup>, is concerned with the physical behaviour and fate of the fission debris produced during the nuclear explosions of 1961 and 1962. This debris is significant, primarily because of the potential radiological hazard to human populations but also because of its usefulness as a meteorological tracer. It is convenient to divide the debris into tropospheric and stratospheric components. The tropospheric debris remains in the troposphere after the cloud has stabilized, is dominated by short-lived radioactivity and could be observed during periods in 1961, 1962 and 1963 without interference by tropospheric debris from the earlier tests that had disappeared by decay. Stratospheric debris originates from the portion of the cloud that penetrates into the stratosphere and remains for a period, dependent on the latitude and altitude of injection, long compared with the residence time of tropospheric debris. It follows that when the new stratospheric debris has returned to the troposphere it is accompanied by a background of long-lived fission products from the residue of stratospheric injections of past years.

## Tropospheric Fission Products

In the troposphere, which in the middle and high latitudes extends to 10–14 km, the wind field varies with level so that debris injected at different levels will be carried on different tracks. Although vertical motion is very slow in comparison with horizontal winds, the cloud of debris will be spread over a very large area of complex shape after several days. Twice-daily charts of the wind distribution over the northern hemisphere are drawn in the Meteorological Office from routine observations for a series of standard upper levels. Vertical motion, too small to be observed directly, may be inferred at least qualitatively. Thus, in the lower half of the troposphere surface anticyclones are associated with slow descent of air, which if continued over several days may bring down debris from great heights to near the surface. Slowly ascending air is associated with the extensive cloud and rain areas of depressions, but in this case wash-out by precipitation counteracts upward transport.

In middle and high latitudes the average circulation is circumpolar from west to east, although frequently subject to large and changing disturbances. In the lowest levels these disturbances are often closed circulations—anticyclones and depressions—which, over limited sectors,

reverse the general west-to-east flow or give rise to broad meridional currents. At higher levels the circulations are replaced by wave-like features in the westerly current, having a wave number for the complete hemisphere of three to six. The westerly component of wind usually increases with height, reaching a maximum near the tropopause; easterlies present at the lowest levels tend to decrease with height and reverse at some upper level.

*Trajectories.* Debris from nuclear explosions will therefore usually reach the British Isles from the west and, in the case of explosions at the Russian testing sites in the Arctic (75° N., 55° E.) and in Central Asia (52° N., 78° E.), will have made nearly a complete circuit of the hemisphere in a time between 12 and 25 days dependent on season, level and the strength of the large-scale circulation. Occasionally debris from the Russian sites will reach the British Isles on more direct tracks from between east and north with a shorter transit time, particularly material injected into the lower levels of the troposphere.

The activity of barium-140 (half-life 12.8 days) may be considered as representative of short-lived fission products. The daily fluctuation in surface air at Chilton (52° N., 1° W.) is illustrated in Fig. 1 together with the ratio of barium-140 to zirconium-95 (65 days)<sup>2,3</sup>. It is clear that the source of barium-140 activity and hence of tropospheric debris detected at Chilton was the explosions at the Russian sites. No significant short-lived activity from the American explosions during 1962 (at Johnston Island, 17° N., 169° W., and Christmas Island, 2° N., 157° W.) was measured in the United Kingdom during March–August.

The general correlation of these fission product parameters with average wind speeds in 1961 has already been investigated<sup>1</sup>. For the tropospheric debris from the Russian series in the autumn of 1962 it has been possible in a few cases to track the path of a cloud from the United Kingdom to the testing site. A trajectory at about 5.5 km (500 mb) drawn in Fig. 2 is related to the peak of barium-140 about October 6–9, 1962. The trajectory was obtained by back-tracking from southern England from October 6 using the twice-daily routine charts of winds and contours. Over the Pacific and east Asia the tracking was less uncertain than usual—most trajectories cannot be tracked realistically much beyond the west coast of North America—and it is likely that the trajectory passed near central north China on about September 26. At that time the wind over northern Siberia was north-westerly, so that the corresponding trajectory was probably like the broken line in Fig. 2. After allowing an uncertainty of one or two days in timing it seems reasonable to associate the large explosions at Novaya Zemlya on September 25 and 27 (ref. 8) with the enhanced air concentrations in the United Kingdom about 12 days later.

The two trajectories shown in Fig. 3 are shorter ones. The first was constructed by forward-tracking from a known explosion of intermediate yield in central Asia on November 4, 1962 (ref. 8), to which are attributed the markedly enhanced concentrations of barium-140 at Chilton on November 10 and at other stations in the United Kingdom during the week November 5–11. The geographical distribution<sup>3</sup>, with very high concentration in the extreme north (Lerwick), high values in the north (Eskdalemuir) and east (Orfordness) and smaller but still

Fig. 1.  $^{140}\text{Ba}$  and  $^{95}\text{Zr}$  in air at Chilton

enhanced values in the south (Chilton) and west (Milford Haven), may be qualitatively explained by a lateral falling-off of activity from the centre line of this trajectory. The high levels of activity and the lack of spatial uniformity are consistent with a low cloud of fresh debris: in fact, over central Asia the easterly winds near the surface changed to westerly at about 2.5 km. The second trajectory in Fig. 3 was obtained by back-tracking at about 5.5 km (500 mb) from Chilton on December 29, 1962, when there was a peak in barium-140 concentration. The trajectory started from explosions in Novaya Zemlya on December 24 or 25 (ref. 8), passed round the pole in the Siberian-Canadian sector and approached the British Isles by northern Greenland and western Norway.

A trajectory for the first Russian test explosion in 1961 has been published by Machta *et al.*<sup>9</sup>: Hvinden *et al.*<sup>33</sup> have described the passage of a radioactive cloud over Norway in November 1962.

**Fission product ratios.** The transport may be timed in a more general way by examining in Fig. 1 the ratio barium-140 to zirconium-95, which has a value of 5 (ref. 10) at the time of formation during fission. Apart from an anomalously high initial value in September the ratio in 1961 tended during the first few weeks to 2.5, which would correspond to a transit time of 16 days. This represented debris passing Chilton during a first circuit; subsequent dilution of first circuit debris by debris on second or later circuits caused a gradual decrease in the ratio until mid-November 1961, the time of arrival of debris from the last explosion in the 1961 series. After this time the ratio of barium-140 to zirconium-95 decreased with the characteristic radioactive decay implying uniform mixing with debris from previous explosions: meanwhile the barium-140 activity was removed from the troposphere at a slower rate (Fig. 1) than required

Fig. 2. Trajectory at 500 mb (5.5 km), September–October 1962

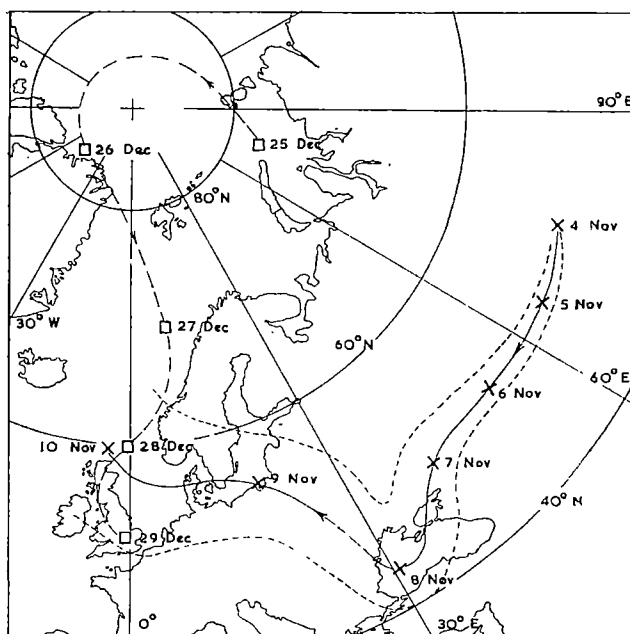

Fig. 3. Trajectories: November–December 1962. □, 500 mb (5.5 km), December 25–29, 1962; x, &lt;2.5 km, November 4–10, 1962; ---, rough indication of spread

Fig. 4. Dry deposition velocity and mean effective particle diameter (Chilton)

by the combined effects of radioactive decay (half-life 12.8 days) and wash-out (half-residence time 20 days<sup>11</sup>). This evidence strongly suggests the onset by mid-November 1961 of significant reinforcement of the troposphere by stratospheric debris. It is remarkable that the stratospheric source, composed of debris from so many explosions, should have become so well mixed so soon. The behaviour of the barium-140/zirconium-95 ratio in the autumn of 1962 followed a similar pattern. The purely tropospheric régime lasted from August to early November, although the ratio fell gradually from an initial value that was lower than in 1961 due to dilution by old zirconium-95, residue of the 1961 test series<sup>8</sup>. The stratospheric régime started in early November 1962 and continued through the substantial addition from the explosions in late December 1962 and hence overlapped the tropospheric period by about three months.

**Dry deposition.** An important characteristic of a period of tropospheric fall-out is the increase in the rate of dry deposition; this characteristic has become well established during the test series of 1961 and 1962. The effect of dry deposition may be observed by the deposition velocity<sup>12</sup> (cm-sec<sup>-1</sup>) given by:

$$\frac{\text{rate of dry deposition (pc.-cm}^{-2}\text{-sec}^{-1})}{\text{concentration in air (pc.-cm}^{-3})}$$

and has been measured at Chilton by exposing artificial surfaces beneath a rain shelter<sup>7</sup>. The variation of dry deposition velocity on to a horizontal sheet is shown in Fig. 4; increases sometimes ten-fold occur during the tropospheric periods. At the same time the 'mean effective' diameter of the airborne particles was determined by measurement of the retention efficiency of the filter media at various air speeds<sup>8</sup>.

It is clear from Fig. 4 that the increase in particle diameter is accompanied by an acceleration of dry deposition. It is not possible to account for the dry deposition velocity at any time by gravitational settling, since the terminal velocities, calculated by Stokes's Law, are much smaller than the observed deposition velocities. Presumably alternative processes such as diffusion and impaction<sup>12</sup> are mainly responsible; these processes must react sharply to the changes in particle diameter that are shown in Fig. 4. Conditions most favourable to enhanced dry deposition are produced in low-level clouds of fresh debris on more direct trajectories, which could account for the peaks in October 1961 and in October and November and December 1962 (Fig. 3) but not for September

1962. The increase in dry deposition has practical significance for the short-lived fission products, for example iodine-131 (8.1 days), that dominate the tropospheric debris, in that the dry deposition rate at Chilton (annual rainfall, 60 cm) approaches the rate of wash-out by rain<sup>7</sup>.

### Stratospheric Fission Products

In the long term the stratospheric component of nuclear debris is obviously more important both for meteorological tracer investigations and for the assessment of radiological dose. However, for reasons of expense and practicability it has been possible to measure this debris adequately and continuously only as it appears in the troposphere; its stratospheric history must be deduced mainly from these measurements in the troposphere.

#### *Caesium-137 in surface air at Chilton.*

The concentration in surface air at Chilton of the long-lived fission product caesium-137 (30 years) recorded in Fig. 5 continues to demonstrate the annual oscillations observed by Stewart *et al.*<sup>13</sup>, although with peaks in 1962 and 1963 that are broader than in previous years. The end of the first phase of nuclear weapon testing was marked by an intensive series of explosions at the Russian sites in the autumn of 1958. In the following year the concentration of caesium-137 in air rose to an unprecedented maximum value (Fig. 5), fell rapidly to low but sustained levels during 1960-61, a quiescent period apart from minor explosions at French sites in Africa, and then late in 1961 rose in response to the latest phase of weapon testing.

Additional information may be extracted from these measurements by considering the ratio to caesium-137 of the shorter-lived fission product cerium-144 (285 days). The earlier behaviour of this ratio has been discussed in a previous paper<sup>14</sup> in which it was shown that the discontinuity and downward displacement in the curve for cerium-144/caesium-137 (Fig. 5) in mid-1959 corresponded to a substantial reduction in the proportion of Russian 1958 autumn debris and to a virtual exhaustion of the source of new debris in the lower stratosphere. It was then postulated that the uniform mixture (effective date of origin about January 1958) during the following two years contained only a minor contribution from the most recent explosions but consisted mainly of older debris from *Hardtack* (1958), *Redwing* (1956) and *Castle* (1954) presumably lodged in the upper stratosphere.

The mixing ratio of debris during this period was unaffected by the annual reinforcement of the lower stratosphere during the winters of 1959-60 and 1960-61. The mixture was, of course, violently disturbed by the later phase of nuclear weapon testing that started in September 1961. The relative amount of fresh long-lived radioactivity may be estimated from the ratio cerium-144/caesium-137 in Fig. 5 or from other fission product ratios<sup>4,5</sup>. The proportion of new caesium-137 in 1962 was not less than 60 per cent. The fission product ratios plotted in Fig. 5 also show that, at least until the next Russian test series started in August 1962, no radioactive material from the present American explosions at the equatorial test sites was transferred to the latitude of the United Kingdom. In 1963 the proportion until mid-year from the Russian series of 1962 was 75 per cent; the remainder was due to debris from the American 1962 series together with that from before 1962. These proportions may be used to estimate the continuing contributions of aged debris revealed in 1960-61. It can be shown<sup>4,5</sup> that the level of caesium-137 of pre-1961 vintage continued

Fig. 5.  $^{137}\text{Cs}$  and  $^{144}\text{Ce}$  in air at Chilton

without appreciable diminution into 1962 and, with greater uncertainty, into 1963 (Fig. 5). This is evidence of a long residence in the upper atmospheric reservoir of the earlier debris, evidence that is supported by other work, for example, by Gustafson *et al.*<sup>15</sup> and Lockhart *et al.*<sup>16</sup>. Since 1961 manganese-54 has appeared in samples of fall-out. If this nuclide is, as reported<sup>15,17</sup>, peculiar to the 1961 Russian explosions as a high-altitude tracer, then its behaviour is consistent with a long residence time in the upper atmosphere<sup>6</sup>.

The curves of fission product ratio used as described here to estimate the proportion of new debris show an additional feature that is important in the interpretation of atmospheric behaviour. Thus in the first halves of 1959, 1962 and 1963 the mixing ratios given by the cerium-144/caesium-137 ratios of Fig. 5—or more precisely by the shorter-lived and more sensitive ratios zirconium-95/caesium-137 and strontium-89/strontium-90 (refs. 4, 5 and 18)—reached uniform values during or immediately after the tropospheric periods of the preceding autumns. This rapid approach to a homogeneous mixture applies both to fresh debris injected into the lower stratosphere from equatorial and arctic latitudes (1959 and 1963) or to the mixing of fresh debris with the annual increment of old debris.

Another aspect of atmospheric mixing that has even greater significance in the long term is demonstrated by the behaviour of the fission product ratio at mid-year in 1959 and 1963, when the new debris directly injected into the lower stratosphere has been exhausted and is then succeeded by debris transferred from the long residence store above. In contrast to the reduction in cerium-144/caesium-137 ratio in 1959 noted here, the ratio increased slightly in mid-1963 to a value corresponding to a proportion of caesium-137 from the 1962 Russian series of ~90 per cent; this proportion has been sustained at least until the autumn of 1964. The implication of this increase in mid-1963 is that the upper atmospheric store, assumed to be responsible for the regular seasonal pattern of caesium-137 in 1960–61, has been massively reinforced at least for the 1963–64 season. The surface air concentra-

tion of caesium-137 observed in 1964 is consistent with the current proportion of 1962 Russian debris after allowing for a diminution of the 1960 level to (say) two-thirds by 1964 (corresponding to a mean residence time of 10 years). This comparison is uncertain because of the unknown but probably small contribution from the high-altitude component of the other recent series.

The meteorological significance of the fission product ratio and its effect on estimates of the content of the atmospheric reservoir will be discussed later.

**Measurements at other stations.** The results already discussed here for the Chilton samples may be compared with measurements made in samples from other stations in the United Kingdom and also from the network of rain collectors overseas<sup>6</sup>.

The annual mean value of caesium-137 in surface air at Chilton lies within 20 per cent of the average value for all the stations<sup>4,6</sup> in the United Kingdom (five stations in 1963). Similarly the annual mean value of the concentration of caesium-137 in rain collected at Milford Haven (52° N., 5° W.) lies within 20 per cent of the average value for all the stations<sup>4,6</sup> in the United Kingdom (ten stations in 1963). The annual mean values since 1954 of caesium-137 at Chilton are shown in Fig. 6 together with other parameters; the variation of caesium-137 in surface air at Chilton followed generally that of the peak value each year<sup>6</sup>. The ratio of the concentration in the composite sample of effective altitude 1.3 km over the eastern Atlantic to that at ground level (for equal masses of air) is a measure of the gradient of caesium-137 in the troposphere. This ratio had a steady value about 2.5, but then rose during the latest phase of nuclear testing. The increase in gradient was unlikely to have been caused solely by an additional burden, compared with previous years, of tropospheric debris directly injected, but probably reflected a source of debris in the stratosphere that was substantially sustained beyond the season of injection. The ratio of caesium-137 in rain (at Milford Haven) to that in surface air at Chilton (for equal masses of rain and air), conventionally defined as the 'wash-out factor', varied slightly about 700, but increased to 1,100 when the new

Fig. 6. Annual mean values

- A,  $^{137}\text{Cs}$  in air at Chilton (pc./kg)

debris appeared during 1962–63. The increase of the conventional wash-out factor with increase of gradient in the lower troposphere suggests that the true wash-out factor related to the air concentration at some indefinable rain-forming altitude has remained unchanged. An alternative explanation based on anisokinetic sampling of the larger particles of debris since 1961 would account for both the apparent increases in gradient and wash-out. However, the increase in particle size shown in Fig. 4 is probably insufficient to explain the magnitude of these effects.

The relation between fission product concentrations measured in the United Kingdom and overseas may be derived from the strontium analyses of rain-water collected at about 25 stations<sup>5</sup>. The variation with latitude of the concentration of strontium-90 (28 years) in rain is shown in Fig. 7 for the two halves of 1962. The curves show the well-marked dependence on latitude observed by Stewart *et al.*<sup>13</sup>, namely, a peak in middle latitudes of the northern hemisphere and low concentrations in the southern hemisphere falling to virtually zero in the equatorial region. In addition there is some evidence of a rise northwards of 60° N. The seasonal variation is demonstrated over most of the northern hemisphere; the reversal of this relationship in the southern hemisphere, which would correspond to an out-of-phase seasonal variation, may be due to tropospheric debris from the American test series during 1962. Similarly the peak in the northern hemisphere in mid-latitudes in the second half of the year, contrary to 1958–59 (ref. 14), may have been enhanced by tropospheric debris from the 1962 Russian test series. To reduce the effect of local variations the annual comparison made in Fig. 6 is between the integrated global deposition of strontium-90 and the concentration in rain at Milford Haven. The global deposition<sup>6</sup> is obtained by integrating the latitudinal distribution of strontium-90 concentration in rain weighted by the distribution of rainfall with latitude<sup>19</sup> over the Earth's surface. In Fig. 7 the latitude distribution

of strontium-90 deposition for 1962 shows the same peak in mid-latitudes as does the concentration, with less-marked variation due to the modifying influence of the distribution of rainfall and surface area with latitude. The global integration is uncertain because of incomplete coverage by the measuring stations, including none over the sea which covers two-thirds of the Earth. Nevertheless, within this recognized limitation the strontium-90 ratio, nominal global deposition/concentration in rain at Milford Haven has varied by less than 50 per cent about  $1.7 \times 10^{17}$  l. during the period 1954–63. An integration by Collins<sup>20</sup> using American data from a greater number of sampling stations gives values of the annual global deposition of strontium-90 that are generally 20 per cent lower than those used here.

Having related the United Kingdom and overseas stations quantitatively, it is now of interest to make a qualitative comparison of effective age or origin of debris by investigating fission product ratios on the global scale. As a preliminary it is necessary to note that the behaviour of the fission product ratio strontium-89 (50.4 days) to strontium-90 in rain at Milford Haven behaved generally as the ratios zirconium-95/caesium-137 (ref. 6) or cerium-144/caesium-137, shown in Fig. 5, in surface air at Chilton. The variation with latitude of the ratio strontium-89/strontium-90 in rain<sup>4–6</sup> is illustrated in Fig. 8 from September 1961. Except during periods of weapon testing the ratio continued to be independent of latitude in the northern hemisphere, again demonstrating uniform mixing of debris<sup>14</sup> from the equator to 70° N. despite the marked dependence on latitude of strontium-90 shown in Fig. 7. There was no substantial transfer of Russian debris across the equator, although the rapid minor excursion during September 1961 (ref. 4) has considerable meteorological interest. The American explosions during April–November 1962 increased the ratios in the equatorial region, with greater proportionate effect in the southern hemisphere.

### Atmospheric Mechanisms

The introduction of artificial radioactivity from nuclear weapon tests has added to the methods available for tracing atmospheric movements. Thus fission products formed in the troposphere and stratosphere may be investigated in conjunction with the radioactivity produced by cosmic rays (stratospheric), radioactivity from radon emanation (terrestrial), water vapour (terrestrial)

Fig. 7.  $^{90}\text{Sr}$  in rain versus latitude, 1962

Fig. 8.  $^{88}\text{Sr}/^{90}\text{Sr}$  in rain versus latitude. ○, uncertain ratios due to low activity

and ozone (stratospheric) in order to follow the movement of air masses on a global scale.

**Transfer from stratosphere to troposphere.** The distinction between the behaviour of tropospheric and stratospheric debris was established by Stewart *et al.*<sup>11</sup>, who demonstrated that the fission products from low-yield tests in Nevada in 1951 had a mean residence time in the troposphere of about one month assuming exponential removal, whereas debris from the high-yield tests near the equator in 1954 returned to ground much more slowly. The mean residence time of one month in the troposphere has been implicitly applied also to debris transferred from the stratosphere. The principal agent of removal is rain; the mean residence time of water vapour is 10 days<sup>21</sup>.

Debris injected directly into the troposphere will therefore be removed virtually completely after several months; the presence in the troposphere of continuing fission product radioactivity with a regular seasonal variation must therefore be explained by transfer of debris from the stratosphere through the tropopause, conventionally regarded as a semi-permeable boundary. The mechanism of this transfer is not clear owing to the lack of direct experimental measurements in the vicinity of the tropopause, but the overall characteristics of the process may be calculated using an extension of the method of Staley<sup>22</sup>.

Thus the rate of change of fission product concentration  $C$  in surface air is given by the rate of transfer of stratospheric concentration  $S$  less the rate of removal from the troposphere:

$$\frac{dC}{dt} = KS - kC$$

where  $K$  is the fractional rate of net transfer across the tropopause and  $k$  the fractional rate of removal from the troposphere to the ground. Let the transfer activity  $K$

and the stratospheric concentration  $S$  be represented by sinusoidal factors such that:

$$\frac{dC}{dt} = \text{const.} \times [1 + a \sin(\omega t + \alpha_1)] [1 + b \sin(\omega t + \alpha_2)] - kC$$

where  $\omega = 2\pi/12$  (or  $30^\circ$ ) when  $t$  is measured in months.

Each sinusoidal factor describes a variation about a mean value having a period of one year and a phase angle measured from January 1. For the purpose of this calculation the removal factor  $k$  is considered independent of time and no attempt is made to account for the variation of each term with latitude. After multiplication:

$$\frac{dC}{dt} + kC = \text{const.} \times [1 + A \sin(\omega t + \phi_1) + B \sin(2\omega t + \phi_2)]$$

where the amplitudes  $a$ ,  $b$  and phase angles  $\alpha_1$ ,  $\alpha_2$  may be derived from  $A$ ,  $B$ ,  $\phi_1$  and  $\phi_2$ . Integrating, the steady state solution for  $C$  is given by:

$$C = \text{const.} \times \left[ \frac{1}{k} + \frac{A}{(k^2 + \omega^2)^{1/2}} \sin(\omega t + \phi_1 - \psi_1) + \frac{B}{(k^2 + 4\omega^2)^{1/2}} \sin(2\omega t + \phi_2 - \psi_2) \right]$$

where  $\tan \psi_1 = \omega/k$ ,  $\tan \psi_2 = 2\omega/k$ . The 12 measured monthly mean values of the concentration of caesium-137 in surface air at Chilton in 1963 have been fitted by the method of non-linear least squares to this expression. In principle it should be possible to extract values for the five unknowns—two amplitudes, two phase angles and  $k$  the tropospheric removal factor. However, the minimization process proved insensitive to variation in  $k$ , so it was necessary to assign an arbitrary value to  $k$  and then determine the other four parameters.

The result of the analysis, after putting  $k=1$ , that is, by assuming a mean residence in the troposphere of one month, is shown in Fig. 9. The lower pair of curves represent the stratospheric concentration and the transfer activity: the upper pair represent the measured values and a curve fitted to the computed values. Mathematically the two lower curves are interchangeable, but it seems reasonable to have the concentration in the lower stratosphere peaking in January–February in accordance with measurement<sup>23</sup> and the meteorological evidence of a winter subsidence.

This choice requires the curve of 'transfer activity' to peak in June–July. Staley has suggested<sup>22</sup> that the mechanism of transfer from stratosphere to troposphere was by baroclinic disturbances having maximum intensity in winter, in association with vertical movement of the tropopause, having maximum altitude in summer<sup>24,25</sup>—except in the equatorial region—thereby exposing air formerly in the stratosphere to tropospheric weathering and wash-out. The transfer activity curve of Fig. 9 is in phase with the variation of tropopause height but out of phase with the disturbance intensity, implying that the former effect is more important in transferring debris from stratosphere to troposphere. Similar curves, derived from analysis of the Chilton data for other years, show phase angles and relative amplitudes similar to 1963. The sinusoidal representation is an over-simplification since, for example, the lower stratospheric concentration probably has a sharper pulse-like shape<sup>23</sup>; this may explain the conflict with the meteorological evidence. Nevertheless the curves derived in Fig. 9 provide an explanation of the 3–4 month lag (in United Kingdom latitudes)<sup>23</sup> between maxima in the long-lived fission product concentrations in the lower stratosphere and troposphere. Furthermore, in the curve of lower stratospheric concentration the minimum in July–August (in the case shown in Fig. 9 for 1963) marks the end of the stratospheric 'season'. This is the time of year when the current store of debris has been exhausted and replenishment from the upper atmosphere is about to begin, with debris possibly

Fig. 9. Analysis of seasonal variation; Chilton, 1963

of a different mixing ratio or effective age as in 1963 (younger) or 1959 (older) but of the same age in 1960 and 1961 (Fig. 5).

This treatment of the mechanism of transfer between stratosphere and troposphere does not specify any variation with latitude. The existence of a latitude effect is indicated by Fig. 7; thus the peak of strontium-90 in middle latitudes is probably associated with the major gap in the tropopause and also with the tropospheric circulation system. Since the mixing ratio is independent of latitude, as shown by the strontium-89/strontium-90 ratios in Fig. 8, then the debris must be well mixed before distribution over the hemisphere.

**The stratosphere.** The model most suited to explain the behaviour of nuclear debris in the stratosphere seems to be that of meridional circulation limited in altitude. The circulation was originally postulated by Brewer<sup>26</sup> to explain measurements of humidity, and extended by Dobson<sup>27</sup> to account for seasonal variations in ozone. In the Dobson-Brewer circulation air rises through the equatorial tropopause, moves polewards and subsides into the lower stratosphere of temperate latitudes in late winter or spring. Goldsmith and Brown<sup>28</sup> proposed that the circulation did not extend upwards above roughly 25 km in order to accommodate, *inter alia*, the stationary behaviour of tungsten-185 tracer at the higher altitudes as observed by Feeley and Spar<sup>29</sup>, who considered that this behaviour was best explained by turbulent mixing rather than by an organized meridional circulation. In this compromise the circulation becomes slower with increasing altitude until above 25 km mixing is by small-scale turbulent diffusion or gravitational settling. The stratosphere, which is characterized by a zero or positive temperature gradient, is therefore seen as two regions. The lower region is affected by tropospheric circulations but is not mixed so rapidly as the troposphere, which has a

negative temperature gradient; in the upper stagnant region mixing is inhibited by the temperature structure. Exchange will occur between regions by limited vertical mixing and on a larger scale by subsidence in late winter at polar latitudes. Murgatroyd and Singleton<sup>30</sup> suggest that the subsidence extends above the stratosphere (above 50 km) into the mesosphere.

The evidence presented previously (see preceding section on "Stratospheric Fission Products") gives qualitative support to this model. The seasonal peaks observed (Fig. 5) in the troposphere—only wholly meteorological during 1960–61 and 1964 in that the amplitudes were not enhanced by recent injections—continue to support the concept of a phased polar subsidence. The lower stratosphere mixes debris injected at equatorial and arctic latitudes over a period of six months but only within the hemisphere (Fig. 8). The uniformity of mixing demonstrated by the fission product ratios after mid-1959 until disturbed by the new explosion series, and after mid-1963 relates to debris stored in the upper atmosphere. It is difficult to reconcile this homogeneity of debris of such different ages with the characteristics of the upper stagnant region of the stratosphere. It is possible that the high-altitude debris penetrated into the mesosphere where comparatively rapid mixing is permitted by a reversal of the temperature gradient to negative values. In such an extension to the stratospheric model, as invoked by Kalkstein<sup>31</sup> to explain the distribution of rhodium-102, the reservoir of nuclear debris would lie above the stratosphere, the upper stagnant region

of which would serve as a buffer rather than as a store. If the mean residence time in the reservoir is taken to be 10 years (nominal), then the annual winter subsidence would remove about 10 per cent downwards to the lower stratosphere for subsequent distribution to the troposphere.

Having established that the debris sampled in the 1963–64 season originated at high altitudes, it is now possible to estimate the content of the atmospheric reservoir, again assuming exponential depletion, by comparison of caesium-137 concentrations in air (Fig. 5) and the estimates of the global deposition of strontium-90 (ref. 6). The mean concentration of caesium-137 in air at Chilton during 1964 will probably lie between that for 1962 and 1963. The corresponding global deposition derived from the average for these two years<sup>6</sup> would be about 2.5\* megacuries (Mc.) of strontium-90; one-tenth of this (= 0.25 Mc.) would represent the contribution from the aged debris of the period 1960–61 (see preceding section on "Caesium-137 in Surface Air at Chilton") and is consistent with a mean residence time for that debris of 10 years. The reservoir of aged debris therefore contains  $10 \times 0.25 = 2.5$  Mc. If the newer debris from the 1962 Russian explosions is effectively exhausted during 1964, which is unlikely, then the total reservoir at January 1964 is  $2.5 + 2.25 = 4.75$  Mc. However, the trend of the fission product ratios up to the autumn of 1964 suggests that the 1962 Russian debris has reinforced the reservoir more permanently. In this case the content, again assuming a nominal 10-year mean residence time, would be  $10 \times 2.5 = 25$  Mc. of strontium-90. In this manner it is possible to extract two estimates for the reservoir of strontium-90 at January 1964, namely, a lower limit\* of

\* Volchok—*Science*, 145, 1451 (1964)—extrapolates from the New York deposition and predicts that the global deposition of strontium-90 in 1964 will be 2.48 mc.

4.75 Mc. and an upper limit of 25 Mc. For comparison the cumulative global deposition at this time was nearly 10 Mc. (ref. 6). According to Machta *et al.*<sup>32</sup> the atmospheric inventory in January 1963 was 6.6 Mc.: this reduces to about 4 Mc. in January 1964 after subtracting the 1963 deposition<sup>6</sup>. This inventory is based on sampling by aircraft and balloon up to 30 km and would ignore any debris stored, as postulated here, in the upper stratosphere or mesosphere at ~50 km.

Because of the well-marked seasonal behaviour observed in the troposphere it is clear that the bulk of each annual increment from upper to lower stratosphere occurs by the winter/spring subsidence. It is possible that more continuous delivery also occurs by turbulent diffusion and gravitational settling that might account for the shallowness of the autumn trough observed in 1963 (Fig. 5). Comparison of the effectiveness of diffusion and gravity is prevented by the lack of experimental estimates of the size of the particles while in the stratosphere. By calculation of the time of fall from, say, the top of the stratosphere at 50 km to the bottom of the stagnant compartment at 25 km, it can be shown that, at present, gravity would have had significant effect for particle diameters (unit density) in the stratosphere of ~1 $\mu$ . For the aged debris observed in the troposphere in 1961 the corresponding lower limit to particle size while in the stratosphere tends towards 0.1 $\mu$ . The 'mean effective' particle diameter<sup>6</sup> observed since 1958 near ground-level (ignoring tropospheric debris) lies in the region 0.4–0.8 $\mu$  (Fig. 4); this includes the effect of coagulation after the particles have entered the troposphere. It follows that the existence of a significant gravitational component in the upper stratosphere is possible in 1961 but improbable during 1963–64.

We thank Dr. A. G. Forsdyke and Dr. R. J. Murgatroyd of the Meteorological Office at Bracknell for their advice. Dr. Forsdyke provided the meteorological material for the discussion leading up to and including the trajectories of Figs. 2 and 3.

## FOREST GROWTH AND GLACIER CHRONOLOGY IN NORTH-WEST NORTH AMERICA IN RELATION TO SOLAR ACTIVITY

By DR. J. R. BRAY

Grasslands Division, Department of Scientific and Industrial Research, Palmerston North, New Zealand

FOR the period A.D. 1750–1960, a correlation of +0.47 ( $P < 0.05$ ) was found between bole growth per decade of forest-grown Engelmann spruce (*Picea engelmannii* Parry) in the Yoho Valley, B.C., Canada, and mean yearly sunspot number per decade<sup>1</sup>. Information on sunspot number from 1700 until 1749 not previously available<sup>2</sup>, together with a sample of *Picea* growth from a nearby area, prompted a reconsideration of this correlation. The additional sample was made in the Little Yoho Valley (51° 31' N., 116° 34' W.) 6 km south-south-west of the Yoho Valley. Increment borings were taken from *Picea engelmannii* which grow in a forest adjacent to the end moraine of the President Glacier<sup>3</sup>. Immediately after each increment core was collected, a drawing of the core was made in order to avoid the distortion in ring width which may occur with differential shrinkage during storage. From these drawings, measurements were made of ring width per decade and the yearly increase in bole basal area per decade calculated by the method previously described<sup>1</sup>.

The result of bole growth measurements in the Little Yoho Valley showed higher growth in late 1700, mid-late

1800 and early mid-1900 and lower bole growth from mid-1600 to early 1700, early 1800 and late 1800. This temporal pattern was similar to that found in the Yoho Valley<sup>1</sup>. For this reason, data on bole growth from the two adjacent valleys were combined (Table 1) for all trees 300 or more years of age (total 49 trees). The correlation coefficient for these data between tree bole growth per sunspot cycle and mean yearly sunspot number per cycle is +0.63 ( $P < 0.001$ ), demonstrating a more significant correlation than in the original investigation.

Trees growing in the Yoho Valley were suppressed in growth up to 150 m from the end moraine during the decade of maximum advance (1840–50) of the Yoho Glacier<sup>1</sup>. Following this decade, forest growth suppression was present only within 5 m of the end moraine. The President Glacier, which advanced in the Little Yoho Valley during 1830–40, had a similar depressant effect on the growth of some nearby forest trees<sup>3</sup>. If tree growth data in Table 1 for the two sunspot cycles during 1834–56 are eliminated because of the growth-depressant effect of nearby glacier ice, then a recalculation of the correlation coefficient between tree growth and mean yearly

\* Sunspot number of 18 estimated for 1964, the probable last cycle year<sup>20</sup>.

† Growth diminished from influence of nearby ice mass.

sunspot number per cycle results in a value of  $+0.76$  ( $P < 0.001$ ).

Since standardized measurements began in 1700, mean sunspot number per cycle has tended to alternate between periods of three or more low-activity cycles and periods of three or more high-activity cycles. Six such periods can be distinguished between 1700 and 1964. The first began in 1724, extended to 1798, and can be separated into an interval of 3 cycles from 1724 until 1755 which had a mean yearly sunspot number of 48 and an interval from 1756 until 1798 which had a mean yearly sunspot number of 57. These intervals were followed by a period of three low-activity cycles during 1799-1833 which had a mean yearly sunspot number of 26. A high-activity period of 4 cycles occurred during 1834-78 which had a mean yearly sunspot number of 56 and which was followed by three low-activity cycles with a mean yearly sunspot number of 35 during 1879-1913. A high-activity period began in 1914, is still occurring, and may extend to near the end of the twentieth century<sup>1</sup>. Mean yearly sunspot number from 1914 until 1964 was 62.

In addition to the foregoing six sunspot periods, two previous periods can be extrapolated from data on sunspot cycle length. From 1699 until 1964, there was a highly significant negative correlation ( $r = -0.53$ ;  $P < 0.01$ ) between mean yearly sunspot number per cycle and cycle-length (Table 1). A closer correlation ( $r = -0.64$ ;  $P < 0.001$ ) existed over the same period between mean yearly sunspot number per cycle and the interval from the maximum of a given cycle to the maximum of the preceding cycle. The lower significance of the correlation between cycle length and sunspot number is the result of the tendency for a high-activity cycle to be longer than is usual when it is followed by a low-activity cycle in which the new sunspots are of low vigour and tardy appearance. An example of this is the high-activity cycle from 1785 until 1798 which had a mean yearly sunspot number of 60, but had an unusually long cycle length of 13.6 years which included an interval of 10.7 years between the cycle maximum and subsequent minimum. The cause of this 10.7 year interval was presumably the tardy appearance of sunspots of the subsequent cycle (1799-1810) which was of very low vigour with a mean yearly sunspot number of 23. The period from the maximum of the 1785-98 cycle to the maximum of the preceding 1776-84 cycle was 9.7 years which more accurately characterizes the vigour of the 1785-98 cycle.

The first of the two extrapolated periods was judged to occur from around 1656 until 1723 and contained 6 cycles of low sunspot activity as determined by: (1) a mean cycle length of 11.3 years and a mean length from previous

to given maxima of 11.5 years; (2) a sunspot dearth reported during 1645-1715 (ref. 4), 1660-1720 (ref. 5) and 1639-1720 (ref. 1); (3) a mean yearly sunspot number for the last two cycles of the 1656-1723 period of 22 (assuming 1699,  $R = 5$ ). The other extrapolated sunspot period was from 1611 until 1655 and was probably of medium activity, since the mean cycle length was 11.0 years and the mean length from previous to present maxima was 11.1 years.

† Neglecting 1834-1850 because of tree growth depression from nearby glacial ice.

‡ Based on 18 trees only, growth relative to 1856-1723.

Mean forest tree growth, in relation to the foregoing eight sunspot periods, decreased with decreasing solar activity per period (Table 2). The sunspot cycle periods in Table 2 were aligned in order of decreasing mean yearly sunspot number which was supplemented by sunspot cycle length for the two periods for which sunspot numbers were not available. Forest tree growth decreased from 9.3 cm<sup>2</sup>/yr for 1914-64 and 9.8 cm<sup>2</sup>/yr for 1756-98 to 8.9 cm<sup>2</sup>/yr for 1879-1913 and 8.7 cm<sup>2</sup>/yr for 1656-1723 and 1799-1833. This relationship was considered to reflect growing season temperature<sup>1</sup>, with higher tree growth likely to occur during a longer and warmer growing season and lower growth to occur during a shorter and colder season. There is, therefore, indirect evidence that summer temperatures in the Yoho area may be related to solar activity, with higher temperatures occurring during periods of greater sunspot number. Yearly world temperature patterns since 1750 have also been tentatively related to sunspot activity<sup>8</sup>. The recent demonstration<sup>7</sup> of atmospheric temperature above 300 km increasing with higher solar activity may provide a mechanism for a solar activity-climate correlation if a connexion can be found between upper air and surface temperatures.

**Glacier chronology.** A shortened season for tree growth is probably coincident with an increased period in spring and autumn when glacier budgets at high elevations are positive. Such an increased ice accumulation period may be sufficient to result in a positive yearly ice budget and, eventually, in ice advance at the terminus. An increased likelihood of ice advance during the close of and following periods of lower solar activity was demonstrated for all maximum advances and major readvances of glaciers in Alberta and British Columbia, Canada, and Washington and Oregon, U.S.A.<sup>1</sup>. To examine further this relationship, dates from subsequent investigations and for minor ice advances were added to the original compilation as follows: subsequent work, major advance, Boulder Glacier about 1750 (ref. 8), President Glacier 1714 (ref. 3); readvance, Boulder Glacier 1850, 1880, 1954 (ref. 8), President Glacier 1832 (ref. 3); minor readvance, Yoho Glacier 1890's, 1914 (ref. 1), Emmons Glacier 1896 (ref. 9), Nisqually Glacier 1893-1907 (ref. 10); Freshfield Glacier 1881 (ref. 11); Helm Glacier 1700-12 (ref. 12); Commander Glacier 1890's (ref. 13), 1954 (ref. 14). A total of 47 dates was available from this compilation.

Sixty-eight per cent of glacial advance since 1640 in the area noted here occurred during 1700-32, 1811-53 and 1890-1914 towards the close of, and immediately following, the three periods of lowest sunspot activity, 1656-

1723, 1799–1833 and 1879–1913. There may be a lag of up to 18 years between a period of heavy snow accumulation in an icefield and the conversion of this snow to ice and its maximum distance flow from the icefield<sup>1</sup>. The existence of this lag period may explain the tendency for glacial advance to occur immediately after, as well as towards, the close of periods of low sunspot activity. In summarizing the glacier chronological dates noted here, therefore, a period of about 15 years (40 per cent of the length of the subsequent period) was added to the close of each sunspot period and subtracted from the following period (Table 2). The result of this manipulation clearly shows a tendency for glacial advance to occur during and immediately after low sunspot periods. There is a  $\chi^2$  of 7.7 ( $P < 0.006$ ) for the hypothesis that an equal number of glacial advances should occur in the 4 high sunspot periods and in the 4 low periods which demonstrates the improbability of the greater number of ice advances in the low sunspot periods occurring by chance.

The majority of data on periods of glacial advance noted here were determined by adding the age of the oldest tree on a given mineral soil surface to the average length of time for tree invasion of that surface following its deposition at the time of maximum ice advance. The most useful mineral surface for this examination was the material of the end moraine on the side away from the ice. This period for tree invasion has been measured or estimated as 5 years on Mount Hood, Oregon<sup>16</sup>, 1–16 years on Mount Rainier, Washington<sup>9</sup>, 30–50 years on Mount Rainier, Washington<sup>10</sup>, 5–23 years for the same area as the preceding investigation<sup>9</sup>, 12–17 years on unspecified sites in the Canadian Rockies<sup>11</sup>, 20–43 years on surfaces of known age in the Yoho Valley, Canadian Rockies<sup>1</sup>, and 25–32 years on the basis of a tree which started growth in 1862 and which grew adjacent to a mature forest in which there was a marked growth decline indicating glacial advance from 1830–37 in the Little Yoho Valley<sup>3</sup>. These results suggest that the period for tree invasion increased from the south to the north and from lower to higher elevations. Other reasons for these differences in invasion period have been discussed<sup>1</sup>. A more rigorous selection of glacier chronologies was made by choosing only dates from direct observation and from information on mature trees which grew immediately outside the glaciated area and which gave evidence for a period of ice advance through: (1) drastically reduced growth caused by cold-air drainage or the nearby presence of ice; (2) drastically increased growth through removal of tree competition; (3) frost cracks; (4) changes in ring pattern through tilting of the bole; (5) scarring from boulders or ice blocks. These dates (last column, Table 2) support the glacier activity–sunspot cycle relationship noted here. More than three-fourths of the glacial advances occurred during 1707–15, 1832–47 and 1893–1914, during the close of and immediately following the three periods of lowest sunspot activity.

**Climatic pattern.** In an analysis of climatic pattern during A.D. 800–1950<sup>1</sup>, evidence was summarized for a period of generally lower solar activity from around 1400–1900. This period was concurrent with a period of increased glaciation in West Greenland<sup>18</sup>, north-west North America<sup>1</sup>, western Europe<sup>15</sup>, the Caucasus and Soviet Arctic<sup>17</sup>, East Africa<sup>18</sup> and presumably elsewhere. Further evidence for a low solar activity during the 1400–1900 period is the length of the sunspot cycle during this period compared with cycle length in preceding and subsequent periods. Data in Kanda<sup>16</sup> on the number of Oriental solar observations from 27 B.C. to A.D. 1930 were analysed for cycle length. Sufficient observations are available to establish cycle length for the fourth, ninth, twelfth and thirteenth centuries (Table 3). If solar observations were separated by more than one-half an average cycle length (about 5 years), they were regarded as representing separate sunspot maxima. The result of this analysis, compared with sunspot cycle lengths during

† Brackets couple observations made during the same sunspot maximum period.

†† Dates with asterisk from aurorae observation, other dates from sunspot observation.

1600–1964 (Table 4), shows that cycle lengths tended to be lower in the fourth, ninth, twelfth and thirteenth centuries than for the 1600–1900 period, and to be more comparable with the period 1900–64. This suggests that in view of the negative correlation between sunspot number per cycle and cycle length demonstrated earlier, sunspot activity in the fourth, ninth, twelfth and thirteenth centuries was higher than for the 1600–1900 period. These results support information on the total number of Oriental solar observations noted earlier<sup>1</sup> and reproduced in Table 4.

Evidence is accumulating that for Asia, Europe, North America and, probably, the southern hemisphere, an era of widespread glacial advance occurred at high elevations from the late fifteenth and early sixteenth centuries to about the end of the nineteenth century. This minor glacial epoch was preceded by a period of 1,000 or more years during which many mountain glaciers were smaller or had completely melted<sup>1,3,15,17,18</sup>. As suggested from the evidence summarized in Table 4, this minor glacial period was apparently synchronous with a period of lower than average sunspot activity. Since 1900 and for many, if not all, of the 12 centuries before about A.D. 1500, there has apparently been a higher average sunspot activity and a period of mainly glacial retreat or stagnation.

I believe this presentation strengthens the evidence previously given in support of the solar radiation climatic hypothesis<sup>1</sup>. During the period 1610–1964 for which sunspot observations are available, the great majority of advances of ice in north-west North America occurred at the close of and immediately following periods of low sunspot activity. Glacial retreat or stagnation occurred during periods of higher sunspot activity. Tree growth in the Yoho National Park area of British Columbia was positively correlated with sunspot activity during this period, which may reflect a relationship between growing season, climate and solar activity. There is also evidence, although fewer data are at present available, that glacial advance during the past several millenia has predominated in centuries of lower average sunspot activity, and glacial

## COMMUNAL FOOD DISTRIBUTION AND DIVISION OF LABOUR IN AFRICAN HUNTING DOGS

By DR. WOLFDIETRICH KÜHME

Max-Planck-Institut für Verhaltensphysiologie, Seewiesen über Starnberg, Germany

IN the Serengeti Plains of East Africa a pack of hunting dogs (*Lycaon pictus lupinus* Thomas 1902) was observed from a specially equipped Land Rover for a total of 523 h between February and May 1964. The pack contained 6 males and 2 females, of which one had 4 and the other 11 pups. These were about 1 and 3 weeks old, respectively, as observations began, and lived in one of the numerous burrows which aardvarks, warthogs, or hyaenas dig in this area. All members of the pack behaved very tolerantly to one another. Only the females had minor disagreements, because they competed in caring for the pups. Each of them nursed all the young and tried to steal them from the others. When the older young at about seven weeks could already run well, lions repeatedly investigated the burrow, causing the pack to move to another burrow about 1,000 yards away from the first. The 4 younger pups were thereupon carried singly in their mother's mouth to the new site. Some days later the pack again moved, and thereafter increasingly readily, until the pack with 3-month-old cubs no longer sought out a burrow to rest, but lay on the grass in the open. Although initially the adults chased off (but did not kill) any hyaena or jackal approaching within a distance of 500 yards from the home burrow, they now allowed these animals to approach within 50 yards of the half-grown pups.

The hunting range of the pack in February, as the great antelope herds trekked across the plains, covered about 20 square miles. In May but little game remained, so the dogs had to extend their forays to an area of 60-80 square miles. Four other packs of hunting dogs adjoined this area. Apparently hunting dogs remain in the same area as long as they can find food there, and there is then no mixing of packs.

The pack had fixed times for hunting—in the morning about sunrise (6.50) from 6.30 until 7.30 and in the evening from 18.00 until 19.00 (sunset at 18.50). Observed hunts were always successful. The numerous Thomson's and Grant's gazelles took flight only when the racing dog pack had approached within 600-800 yards. From this distance, however, a hunting dog can overhaul either of these antelope in direct pursuit. When the pursuer is hard on its heels, the quarry tries to escape by zigzagging and often actually does succeed in gaining some ground. If the hunter has overtaken his quarry two or three times without being able to seize it in the flank, he is so exhausted that he has to give up the chase, panting heavily. Success is more certain when several dogs pursue the same antelope. In its avoiding manoeuvres it is likely to come closer to one of the other dogs, which can then catch it. I never saw a true relay hunt.

Besides gazelles, the hunting dogs killed gnu calves, which they tried to separate from the herd. As soon as

the dog pack approached a herd of gnus, the bulls standing around the edges tried to drive them off by charging. The dogs avoided the attacks and tried each on his own to penetrate to the core of the herd, where the calves and their mothers were congregated. So long as these all packed tightly together the hunters were powerless, but sooner or later a calf broke out of the herd, followed by its mother, and in an instant all the dogs were after it. The mother defended it for a time, but soon followed the stampeding herd. Outside the daily hunting periods, Thomson's gazelles and straying gnu calves several times approached within 300-500 yards of the pack as it lay by the pups' burrow, but were not attacked. At night these visually oriented dogs did not go out hunting.

The quarry was felled by bites in the flanks and hind quarters; as soon as one prey was down, all dogs congre-

Fig. 1. African hunting dogs. Top, male; bottom, female (Photos: W. Kühme)

gated at this kill. A second kill was sometimes made afterwards. The dogs tore open the belly of the still living quarry (without a killing bite) and bolted down hand-sized scraps of meat and skin without chewing. After 5 min they returned to the burrow and disgorged the meat in front of the begging pups and the guards who had stayed behind. Pup-guarding during the hunt was shared in turns by the females and by particular males. The guards could also disgorge in their turn, and when this meat was then taken up by another adult, which passed it on further later on, such a piece of meat could wander through several stomachs before finally being digested. So long as the pups were very small and could not easily swallow the big pieces of meat, the females begged for more meat, which they chewed up and then (over a period of hours) repeatedly disgorged for the pups; they were the storage and preparation containers for the pups' food. The stomachs of all members of the pack, however, served to transport the hastily dismembered prey into safe cover or, when pups were present, into the centre of the pack, where the meat was distributed to begging, and thus hungry, members of all ages. Although the young swallowed meat as early as 14 days, they were suckled for 10–12 weeks. Up to that point they lived in burrows, and there was no indication that they left them to visit water-holes. They were seen to go to water for the first time when they accompanied the adults on their long forays and no longer returned to the burrows. In the first months the pups evidently obtained enough moisture from the fresh bloody meat and from their mothers' milk.

The communal treatment of food supply among pack members made a true division of labour between guards and hunters possible. The first groups of pre-humans

may have formed under similar conditions. A few members of the horde took over as guards the protection of the young, while the rest went about gathering food. In many mammalian societies the greatest share of the food goes to the strongest, dominant individual, generally a male. He then generally has especially important functions within the group. In a pack of hunting dogs all the adults are equally qualified to fulfil any of the functions: catching prey, defending the family, or feeding meat to the young. This ought to require absolute absence of rank, and no indications of rank order were discerned in the pack investigated. One particular male was very often seen in company with one of the females, but did not otherwise stand out in the society. In hunting, at the kill, in distributing the food or during the mid-day sleep at the burrow, all combinations in working and living together were possible. This tolerance of competitors, which human beings find so difficult, was achieved by a special ritual.

In the same way as the pups, the adults also begged from one another, by pushing from the side with the nose against the mouth of the food-bearer and even, in undoubtedly aggressive mood, biting him in the jowls. This juvenile behaviour was also shown by the adults in ritualized form as a greeting, on meeting one another. Not only did they push at one another's jowls, but also a male sometimes licked at the udder of a female, or a female crept under a male as a nursing pup under its mother. All thus behaved rather like children of one great family, in which only the mother occupied a special position, in that she greeted less intensively than the rest.

This work was supported by a research grant from the Fritz-Thyssen Foundation and the Tanganyika National Parks.

## REFLEXIONS ON MANAGEMENT SCIENCE

**I**N his inaugural lecture at the Imperial College of Science and Technology, University of London, on November 3, Prof. Samuel Eilon, head of the Department of Industrial and Management Engineering, discussed the difficulties of defining precisely the scope of his Department. While Prof. Eilon has been variously described as a production engineer, an industrial engineer, an operational research worker, and a management scientist, there is a measure of overlap between these various titles. An authoritative definition by the Institution of Production Engineers states that a production engineer is "one who is competent by reason of education, training and experience in technology and management to determine the factors involved in the manufacture of commodities and to direct production processes to achieve the most efficient co-ordination of effort with due consideration to quality, quantity and cost".

While the knowledge and understanding of production processes are important aspects of the production engineer's work, the definition also stresses the need for managerial competence. Determination of factors which affect production, the characteristics of the product and its cost, the need to plan utilization of resources and to co-ordinate activities—all these call for the same faculties of analysis and synthesis that are expected of a competent manager. Though the definition does not specifically state involvement in human problems or in top management policy decision processes, the understanding of these topics is often implied.

Fig. 1 provides one concept of the interrelation between subjects in which the production engineer is involved, and these can be broadly grouped in two areas.

(a) Production technology, which is the investigation of manufacturing processes and machines, their technical

characteristics and limitations, as well as economic considerations relating to selection of processes and machine utilization. Mechanical processes (such as machining, casting, forming and welding) also play a prominent part in production technology, and chemical and electrical processes could also be added.

(b) Management science, which is the investigation of methods by which industrial activities are planned and controlled. This area could be considered under four headings: First, industrial engineering—a generic term which relates to the methods of planning and control of technical industrial operations, involving men, machinery and plant. This includes organization, production planning, stock control, plant lay-out and materials handling, work study and quality control. Secondly, operational research, or the application of scientific research—analytical, experimental or quantitative—to industrial and business problems with the object of providing a more analytical basis for making predictions and decisions. The third field is that of economics (both macro and micro), budgeting, cost control, industrial law and marketing. The fourth is related to the behavioural sciences, and covers the examination of social and psychological problems of human operators in relation to their work.

One aspect of this approach is worth noting, namely, that all subjects listed in the management science area are equally relevant to industrial situations which do not involve manufacturing processes. Scheduling, for example, is an important function in a factory, where resources of materials, machines and men have to be matched to produce a projected plan of integrated activities; but this is just as important a function in designing a time-table for a construction site, for schools,

Fig. 1. THE RELATIONSHIP BETWEEN MANAGEMENT SCIENCE AND PRODUCTION ENGINEERING

or for a transportation system. The latter are not production activities in the conventional sense, unless the definition of production is stretched to include all service activities.

### Industrial Engineering and Operational Research

Turning to industrial engineering, Prof. Eilon indicated that the difficulties in classifying management or business activities are demonstrated in the attempt made by L. F. Urwick, one of the pioneers of industrial management. He suggested three groups which can be clearly demarcated.

(1) Activities "which were regarded as the professional province of the engineer and as requiring a basic engineering training *before* scientific management was ever thought of", including research and development of natural resources, processing installation and maintenance of plant.

(2) Activities "which belong to one of the major functions of business (accounting, personnel, organization, and the like) and require primarily a training in the basic discipline directly applicable to that function".

(3) Activities which are directly concerned with the effective use of mechanical appliances and, "hence, with their adaptation to the human element in the business complex on scientific lines". Here, "a thorough knowledge of engineering principles and practice, requiring a complete technical training as an *engineer* or corresponding practical experience, have so far proved essential to the most effective performance. . . . It is to this third group of activities that the title industrial engineering is properly applicable".

Urwick also asserted that "engineering as practised by the industrial engineer is only a part of the over-all work of managing. . . . Any title which includes the term *engineering* is strictly limited to dealing with things, because engineering knowledge does not include people".

If Urwick's remarks are accepted as a commentary on the historic development of management, rather than as a doctrine of how it should be practised, his observations may well provide one of the reasons why engineers have been kept away from boards of companies in Great Britain for so many years, and perhaps explains why industrial engineering in the past has adopted a somewhat rigid and mechanistic attitude to managerial problems.

The definition of industrial engineering by the American Institute of Industrial Engineers is as follows: "Industrial engineering is concerned with the design, improvement, and installation of integrated systems of men, materials and equipment; drawing upon specialized knowledge and skill in the mathematical, physical, and social sciences together with the principles and methods of engineering analysis and design, to specify, predict and evaluate the results to be obtained from such systems".

The definition does not specify what size of systems is involved: it could be any size, even encompassing the whole organization. The projected reliance on pure and applied science, as well as social science, and the emphasis given to the investigation of integrated systems certainly puts industrial engineering well beyond the confined boundaries suggested by Urwick. Apart from the puzzling references to "principles and methods of engineering

analysis and design", there are no fundamental features which distinguish industrial engineering from operational research. The latter, defined by the Council of the Operational Research Society, is: "Operational research is the attack of modern science on complex problems arising in the direction and management of large systems of men, machines, materials, and money in industry, business, government and defence. The distinctive approach is to develop a scientific model of the system, incorporating measurements of factors such as chance and risk, with which to predict and compare the outcomes of alternative decisions, strategies or controls. The purpose is to help management determine its policy and actions scientifically". This definition is so broad that it covers practically the whole field of management science.

Similarly, in discussing the relation of economics and the behavioural sciences to management, Prof. Eilon shows wide areas of overlap and how futile it is to attempt to draw clear lines of demarcation. There is a lack of unanimity on terminology, and there are many shades of interpretation of the scope and composition of management science.

The task of management was also discussed. A fruitful way of evaluating the place of various subjects and fields of study in the management matrix is by examining them in relation to the tasks that management has to perform in an industrial enterprise. These may generally be described as: (1) determining the goals of the enterprise (short-term and long-term); (2) planning the acquisition and utilization of resources; (3) instituting recording and communication systems; (4) determining control procedures; (5) evaluating the performance of the enterprise and the effectiveness of the control mechanisms.

This management process can be ascribed to every task of the enterprise, and each stage of this process involves analysis and synthesis, design of alternatives, prediction of the outcome of events, and finally a decision (that is, a selection to be made from the given alternatives). Decision-making is involved throughout the management process, and a great deal of research work has been focused on this area in recent years.

What contributions have modern techniques made to the solution of problems in an industrial enterprise? An investigation of educational programmes in industrial engineering in many universities and colleges (particularly in the United States, where the subject has been taught in the universities for many years) has shown that, until recently, the approach of industrial engineering to management problems has been rather narrowly based and mechanistic in outlook. There are signs that this attitude is now changing.

Similarly, operational research has not yet reached the point where it can unequivocally be acclaimed as indispensable to top management. There are several reasons for this. First, many of the papers which are published in professional journals appear to be increasingly detached from any reality. Some are no more than interesting formal exercises in applied mathematics, written by mathematicians for mathematicians, with little pretence that the discussion could be of use to a practising manager. To do justice to the definition of operational research, perhaps some of this activity should properly belong to

departments of applied mathematics and not be called operational research at all. The true task of the operational research man is to explore reality and build a model to resemble it, not to take a model and try to force reality into it.

Operational research started in industry accompanied by a considerable fanfare to herald its great capabilities to cope with complex problems and large systems having many interdependent variables. Few applications at the strategic level in industry have been made. Most of the attention of operational research workers has been directed to tactical problems, in which the system under scrutiny is well confined and its constraints never questioned. A typical transportation problem in linear programming includes transportation costs in the matrix. It may be more profitable to question these costs, the capacities of transportation media, the capacities of stores and production lines, than to find the optimal solution to the linear programming problem. For many years operational research has been too much obsessed with optimization. It is one thing to find an optimal solution—if it can be found—and it is another to know when and how to implement it. It is only in recent years that adequate attention has been given to sensitivity analysis, that is, to determining what happens when we deviate from an optimum solution and how serious it is. Again, operational research has largely been concerned with the physical environment and tended to ignore or circumvent problems relating to organizational behaviour and to human and social environment.

### Research

Prof. Eilon then went on to describe some of the research topics which are being investigated in his Department. One is management structure and control. There are still many people who believe that management control is a summation of functions, such as financial control, personnel control, production control, etc. Precisely how these tools are co-ordinated and integrated is never made clear. This is not helpful in understanding the intricacies of organizational behaviour, and organization charts have often been shown to be too static, too dogmatic and too naïve to reflect reality.

The mechanistic approach to management is particularly evident on the shop-floor level and is seen, for example, in the attitude to fatigue and rest periods. Yet even the effect of different types of work on fatigue is not adequately known, such as the way an operator's performance is affected by various environmental parameters for a given type of work or the way he is affected by the performance of fellow workers. Barnes investigated the daily product curve for heavy manual work and for light work, and it appears that the latter does not exhibit the deterioration and recovery in production rate, which have been the basic assumptions in many models. Here is a clear example of the limitations of the mechanistic approach to the human machine.

In contrast, there are individuals who regard management control as an applied exercise in sociology, and the coining of the term 'organizational behaviour' is symptomatic of this approach. A survey into management control procedures suggests that they fall into two categories: in the first, an attempt is made to examine the individual within the organization, to record what he does and why he does it, and to assess his role accordingly. Investigations in the second category emphasize relationships between individuals and interpret management control as roles of staff functions, demarcation of responsibilities and lines of communication. Some of these investigations are penetrating and have produced useful results; but the picture remaining of the organizational structure is often too static, leaving the term 'control' ambiguous and undefined.

This is where collaboration between industrial sociologists, engineers and operational research workers could

be useful. One team of research assistants is using the 'tracer' method of investigation, that is, a specific task has been isolated and, throughout its progress, its impact on the organization and the decisions of people have been faithfully recorded. It is too early to attempt to summarize this work; but it appears that some insight is being obtained into the way in which independent control systems emerge and how standards of performance are set. Other topics examined were measurement sensitivity analyses, perishables and semi-perishables, inventory depletion and scheduling.

### On Management Education

Finally, Prof. Eilon examined many aspects of management education. It has been estimated in the United States that more than 60 per cent of graduates with engineering degrees become managers of some kind within 10–15 years after graduation. 25–40 per cent of the entrants to some prominent graduate business schools are engineers, and in institutions like the Massachusetts Institute of Technology School of Management or Carnegie's Industrial Administration, engineers form more than 80 per cent of those registered. No comprehensive surveys have been carried out in Great Britain to show what engineers and scientists actually do in industry. Some investigations show that engineers who reach senior positions spend little time on technical matters and most of their work is administrative in nature. This raises a cardinal issue: if engineers and applied scientists expect to spend so much of their time on management activities, should they not be primed in these matters in the same way that they are being educated in their own specialization? And if they should be so educated, at which stage in their career is it best to do so?

The opposition to academic educational programmes falls, broadly speaking, into three camps: the first objects to any formal training or education in management *per se*; the second asserts that management should be learnt 'on the job'; the third firmly believes that management courses should be organized in industry and taught by practising managers.

It has been argued by members of the first group that management education does not produce managers, that we cannot expect leaders of industry to emerge as a result of a few courses. The question whether management education can produce good managers or not is, however, not relevant. The question is whether it can produce better managers. Naturally, individuals must have a flair for management and certain personal attributes, and without appropriate pre-requisites it is doubtful whether any educational programme can guarantee to produce good managers, good engineers, good doctors, or indeed good practitioners in any field of human endeavour.

Those who oppose formal management education and advocate 'learning on the job' resort to a variety of arguments to prove their point. One is a reference to the famous engineering feats of the past, such as the Great Wall of China or the Suez Canal. These projects were constructed and led by engineers with no sophisticated network analysis and with no special training in management. Even for comparatively small plants we argue that we require managerial expertise and the use of modern management techniques.

Those who argue in this way are not comparing like with like. Competition, the abolition of sweated labour, and the need to treat employees as individual human beings, the necessity to subject most industrial projects to a scrupulous economic examination are such that none of the projects mentioned could be economically and socially feasible in our times with methods of execution used in the past. Industrial operations are getting more complex than ever before, involving an increasing degree of interdependence and technical specialization, and these must be matched by equally sophisticated managerial methods for utilizing available resources. Management is

becoming too difficult for many present-day managers, and by equipping themselves with the appropriate skills they stand a better chance of being effective at their job.

The assertion is often made that management is best taught by practising managers, that the material taught should be based on the lecturer's own experience and that management training is best carried out in industrial firms, using the experience of the firms and their employees. But any manager's experience is necessarily limited by the type of activities he has been engaged on and the kind of situations he has had to face. It is doubtful whether such experience will always be valuable, or even relevant, when this manager and his trainees have to face different circumstances from those recorded in the past. The manager's claim to success does not preclude the possibility that the same level of success, or even better results, could not have been attained by other methods than those he advocates. Moreover, the fact that firms call in industrial consultants, who are not necessarily more mature in years and industrial experience than the firm's own managers, is an admission that other approaches

could be helpful in controlling a changing environment. Resorting to management-training programmes within firms can lead to the worst kind of inbreeding, coupled with stifling of initiative and imagination; and even if his past experience is relevant, the manager is rarely equipped with the skills required to impart his knowledge to others in a systematic fashion or to be an educator.

Industrial firms should re-examine the assumptions on which their management training schemes are based. It would be far better, according to Prof. Eilon, if they were to send their management trainees to a course at an academic institution and then subject them to a short course in the firms, the purpose of which would be to tell these young people about the work and structure of the companies, rather than to teach them their own brand of management.

The form of management education at the university was also examined. Prof. Eilon is doubtful whether the undergraduate student is mature enough to appreciate the implications and ramifications of the subject, and recommends that it should be left to the postgraduate stage.

## OBITUARIES

### Prof. D. D. Woods, F.R.S.

PROF. D. D. WOODS, who died on November 6, 1964, at the age of fifty-two, was the first holder of a chair of chemical microbiology in Britain.

Donald Devereux Woods was a student at Trinity Hall, Cambridge, and obtained first-class honours in both parts of the Natural Sciences Tripos. After graduation in 1933 he began research in the Sir William Dunn School of Biochemistry, Cambridge, where he came under the influence of Sir Frederick Gowland Hopkins and also of Dr. Marjory Stephenson, and it was his association with the latter that led to the development of his interest in the biochemistry of micro-organisms. He obtained the degree of Ph.D. in 1937 and was awarded a Beit Memorial fellowship. He left Cambridge in 1939 to join the Medical Research Council Unit for Bacterial Chemistry at the Middlesex Hospital under the direction of Dr. (later Sir) Paul Fildes. During the Second World War he, together with other members of the Unit, was seconded to the Biology Section of the Chemical Defence Research Establishment at Porton. After the War he was invited by Prof. (later Sir) Rudolph Peters to join the Biochemistry Department at Oxford, where he was appointed reader in microbiology in 1946 and Iveagh professor of chemical microbiology on the endowment of this chair by Arthur Guinness, Son and Co., Ltd., in 1955. He remained at Oxford until the time of his death. He leaves a wife and a daughter.

From the time he first began research, Woods worked on the biochemistry of micro-organisms. During his period at Cambridge, he was mainly concerned with amino-acid and energy metabolism of *Clostridia* and with mechanisms of hydrogen production in bacteria. When he moved to the Medical Research Council Unit, he turned his attention to the nature of the substance present in yeast extract which antagonizes the antibacterial action of sulphanilamide. His demonstration that this substance is *p*-aminobenzoic acid, a structural analogue of sulphanilamide, first brought him international recognition. Together with Fildes, he then put forward the hypothesis that substances which are structural analogues of essential metabolites could inhibit the metabolism of the latter and so prevent growth. This hypothesis proved a great stimulus to research in the design of drugs as "metabolite analogues" and, indeed, the hypothesis has to-day become one of the few principles available for the rational develop-

ment of chemotherapeutic agents. Woods was not able to participate in the early exploitation of the idea, as he was seconded to work at Porton at that time. During the Second World War, workers in the United States showed that *p*-aminobenzoic acid forms part of the molecule of the growth factor folic acid.

When Woods was able to resume academic research in Oxford, he showed that the sulphonamides inhibit the conversion of *p*-aminobenzoic acid to folic acid. Together with research students and colleagues, he then began a series of investigations, using combinations of nutritional mutant and enzymological techniques, to elucidate the biosynthetic functions of folic acid and vitamin B<sub>12</sub>. Investigations of the nutritional requirements of bacteria mutants requiring folic acid or vitamin B<sub>12</sub> showed that both growth factors are involved in the synthesis of methionine from homocysteine. The inter-relationship of folic acid and B<sub>12</sub> proved to be highly complex and was unravelled in a series of papers culminating in three publications in the September 1964 issue of the *Biochemical Journal*. Folic acid is converted to a methyl-derivative as an intermediate, and a B<sub>12</sub>-containing enzyme is necessary for transfer of the methyl group from folic acid to homocysteine. An alternative B<sub>12</sub>-independent pathway was discovered and proved to be uniquely dependent on the triglutamate form of folic acid. The demonstration that some organisms can synthesize their methionine requirement without the mediation of B<sub>12</sub> while others have undergone a mutation to B<sub>12</sub> dependency is of considerable evolutionary interest. In the course of these investigations on methionine synthesis, Woods also made one of the first observations of enzyme repression when he found that growth of organisms in the presence of methionine results in loss of the formation of the homocysteine methylating system. The disentangling of this complex situation bears witness to Woods's skill, intellectual ability and unflinching patience.

Prof. Woods was a Fellow of Trinity College, Oxford, and in 1951 was elected a Fellow of the Royal Society. He gave the first Marjory Stephenson Memorial Lecture of the Society for General Microbiology in 1953 and frequently took a major part in symposia and discussions of that Society. He had a flair for the exposition of difficult biochemical topics, and his lectures were leavened with delightful touches of humour. It is a matter of great regret that he did not live to deliver the Leeuwenhoek

Lecture which he had been invited to give to the Royal Society in December 1964. Apart from his academic activities, Woods sat on many committees and advisory bodies dealing with microbiology and its application; he also carried out considerable editorial work for scientific journals. His many friends and colleagues will always remember his friendliness and enthusiasm for his subject; a long line of successful students will remember his kindly encouragement, advice and guiding hand. He led a full life in pursuit of his subject, and his death leaves a big gap in the ranks of both microbiologists and biochemists.

E. F. GALE

### Prof. L. W. Pollak

PROF. L. W. POLLAK, most widely known for his work in developing the photoelectric nucleus-counter, died in Dublin on November 24, 1964. He was born in Prague on September 23, 1888, and after a distinguished school and college career there was appointed to the staff of the German University in 1911. During the First World War he directed the meteorological service of the German Eleventh Army in the South Tyrol, and afterwards returned to the University, becoming professor of meteorology in 1927 and then director of the Observatories of Prague and Donnersberg.

Pollak's outlook was too liberal to please the Nazi régime, but his students made sure he learned of it when his name went on the list of disapproved persons. He was thus able to escape, and, after some months in London, found congenial employment in the newly formed Irish Meteorological Service, taking up duty at Foyines in December 1939. There he worked alongside Dr. M. Doporto, refugee from Spain, who died in September 1964. Pollak assisted in the teaching of the cadet forecasters, infecting them with his real enthusiasm for meteorology. He next

proceeded to establish the Service's Climatological Division and to initiate its regular publications. In 1947, however, he welcomed the opportunity to regain his standing of professor, as head of the School of Cosmic Physics in the Dublin Institute of Advanced Studies. He quickly built the premises in Merrion Square into an important observatory. The number of students was small, but research continued in many sections of geophysics, while colleagues extended the scope of the School with sections for astronomy and cosmic rays. In 1955 it was the venue for the first International Symposium on Atmospheric Condensation Nuclei.

Pollak retired when seventy-five, but not to laze. He was much in demand as consultant and spent most of his last year assisting projects in the United States. It was, however, at his home that death came suddenly.

Pollak's lectures were prepared with meticulous care, and yet achieved the appearance of spontaneity, and included homely and topical references. Nearly two hundred papers bear his name, many dealing with the photoelectric nucleus counter, developed during his first years in Ireland. It had been the pioneer work on punched-card techniques in climatology which had established Pollak's name earlier, and he was also largely responsible for the dissemination of Fuhrich's auto-correlation method of investigating periodicities. The only text-book bearing his name is *Methods of Climatology*, published in 1950, written in collaboration with V. Conrad, of Harvard University (formerly at Vienna). Many modern instruments incorporate Pollak's improvements: actinometers, balloon theodolites, kata-thermometers, dosimeters, tonometers: all received his attention, and several were the subjects of patents.

His first wife, Johanna, was a gifted linguist. She died in 1958. In 1962 he married Nessa Falconer, who survives him.

F. E. DIXON

## NEWS and VIEWS

### Council for Scientific Policy

THE following have been appointed members of the Council for Scientific Policy: Sir Harrie Massey, Quain professor of physics, University College, London (chairman); Dr. J. B. Adams, director of the Culham Research Laboratory, Atomic Energy Authority; Prof. D. H. R. Barton, professor of organic chemistry, Imperial College of Science and Technology; Prof. P. M. S. Blackett, professor of physics, Imperial College of Science and Technology (also member of the Advisory Council on Technology); Prof. F. S. Dainton, professor of physical chemistry, University of Leeds; Sir Charles Dodds, Courtauld professor of biochemistry, University of London; Prof. K. C. Dunham, professor of geology, University of Durham; Prof. B. H. Flowers, Langworthy professor of physics, University of Manchester; Sir Willis Jackson, professor of electrical engineering, Imperial College of Science and Technology; Dr. F. E. Jones, managing director, Mullards, Ltd.; Dr. J. C. Kendrew, deputy-chairman, Medical Research Council, Laboratory for Molecular Biology, Cambridge; Lord Rothschild, chairman, Shell Research; Sir Gordon Sutherland, Master of Emmanuel College, Cambridge; Prof. M. M. Swann, professor of zoology and dean of the Faculty of Science in the University of Edinburgh. The Council for Scientific Policy will replace the Advisory Council on Scientific Policy and will advise the Secretary of State in the exercise of his responsibility for the formulation and execution of Government scientific policy. Among the issues which are expected to come before the Council will be the balance of scientific effort in the various fields for which the Secretary of State is responsible.

### Operational Research in the University of Birmingham : Dr. S. Vajda

DR. STEVEN VAJDA has been appointed to the newly established chair of operational research in the Department of Engineering Production, University of Birmingham, as from January 22. Dr. Vajda, who was born in Budapest, and who graduated as a Doctor of Philosophy in the University of Vienna, has been head of the Mathematics Group in the Admiralty Research Laboratory at Teddington since 1952. He had previously been a lecturer in the Technical University of Berlin and held various actuarial appointments on the Continent and in Britain before joining the Civil Establishment of the Admiralty in 1944; he was later assistant director of physical research and assistant director of operational research in the Royal Naval Scientific Service. He has been a member of council of the Royal Statistical Society, chairman of the Department of Scientific and Industrial Research Sub-committee on Automatic Data Processing and chairman of the Programme Committee of the International Symposium on Mathematical Programming. His books on mathematical programming and the theory of games have been translated into French, German, Japanese and Russian.

### The Rockefeller Institute : Prof. C. Pfaffmann

DR. C. PFAFFMANN has been appointed vice-president and professor of the Rockefeller Institute, where he will be responsible for the development of a broad programme of graduate teaching and research in the behavioural sciences, with emphasis on the relations of the natural and social sciences. Dr. Pfaffmann graduated from Brown

University in 1933 and was awarded a Rhodes scholarship. He is a member of the American Philosophical Society, the Society of Experimental Psychologists, the American Psychological Association and the National Academy of Sciences. Dr. Pfaffmann is an authority on the physiology and psychology of the senses of taste and smell and the behaviour they control.

#### Prof. M. McCarty

Dr. M. McCarty has been appointed vice-president and professor of the Rockefeller Institute, where he will have primary responsibility for the development of clinical teaching and research and will supervise all its hospital facilities. Dr. McCarty graduated from Stanford University in 1933 and from the Johns Hopkins Medical School in 1937; he joined the faculty of the Rockefeller Institute in 1941. Dr. McCarty is a member of the Association of American Physicians, the Society for American Bacteriologists, the American Association of Immunologists, and the National Academy of Sciences. Together with Avery and MacLeod, he was a pioneer in demonstrating the biological activity and genetic significance of deoxyribonucleic acid.

#### Agricultural Research Council

THE annual report for 1962-63 of the Agricultural Research Council illustrates the continuing wide scope of both basic and applied scientific work carried out in the Council's Institutes and special Units (Pp. iv+91. (Cmnd. 2519.) London: H.M. Stationery Office, 1964. 6s. 6d. net). The appointment of Prof. S. R. Elsdon as the first director of the new Food Research Institute at Norwich and the establishment of the Unit of Nitrogen Fixation under the direction of Prof. J. Chatt at the University of Sussex are recorded. Developments of general interest are the monitoring of radioactivity in foodstuffs; the transmission of a plant virus by the zoospores of a soil fungus; improvements in electron-micrograph techniques for observing virus particles; and the radiometric assay of acetylcholinesterase, the enzyme which provides a chemical link between muscles and nerves in all living animals and which is inactivated by many insecticides. Important developments have been made in the measurement of body temperature by the use of small radio transmitters fitted inside the body and in the screening of drugs, which on administration to the mother may be embryotoxic or teratogenic, by examining changes in the pre-implantation embryo. General accounts are given of work at four institutes, the Animal Breeding Research Organization, the National Institute for Research in Dairying, the Hannah Dairy Research Institute and the Welsh Plant Breeding Station. Summaries of the work of the two units administered by the Council are also included; these are the Unit of Embryology, under Prof. F. W. Rogers Brambell, and the Unit of Plant Physiology, directed by Prof. C. P. Whittingham. The report concludes with appendixes of the committees of the Council expenditures, and special grants in support of research in universities.

#### The Society of Applied Pharmacological Sciences, Milan

A Society of Applied Pharmacological Sciences (Società di Scienze Farmacologiche Applicate) has been established in Milan. The aim of the Society is to bring together, independently of the organizations, institutes or laboratories where they are employed, pharmacologists, microbiologists, biochemists, pathologists, and clinical research workers concerned with research on new therapeutic agents. The Society intends to promote investigations and discussions of all those problems which concern the development of new drugs, and which, in their complexity, are treated only partially by other scientific societies dedicated mainly to basic research. Analysis and discussion of these problems by investigators

who are engaged in evaluating and realizing new drugs are of particular importance at a time when scientific and procedural criteria concerning the introduction of new compounds in therapy are being critically re-examined. The Society hopes to contribute through its activities, in co-operation with the public health organizations, to the greater safety and efficiency of developing new drugs.

#### International Filariasis Association

IN order to promote the investigation and control of filariasis, an association was established, to be known as the International Filariasis Association (Société Internationale des Filarioses). This grew out of earlier meetings held in 1955 and 1961, which were aimed at examining onchocerciasis under the auspices of the World Health Organization. The first general meeting of the Association was held at Rio de Janeiro on September 8, 1963, during the International Congresses of Tropical Medicine and Malaria, and the second at Rome on September 23, 1964, during the International Congress of Parasitology. Further general meetings will be held when international congresses facilitate them. Steps will be taken, as and when possible, to promote the investigation of all types of filariasis through appropriate local meetings, and to provide an official channel for bringing the problems of filariasis to the notice of Governments and international organizations. It is hoped to enlist the interest of all who are concerned with this subject. The officers of the International Filariasis Association are as follows: *President*, Prof. J. F. Kessel (U.S.A.); *Vice-Presidents*, Prof. P. C. C. Garnham (U.K.) and Medical General P. Richet (France). There is an executive council of fifteen members representing the different regions of the world involved, and the secretaries are: Dr. M. Giaquinto (Italy) and Dr. F. Hawking, National Institute for Medical Research, London, N.W.7, from whom further information can be obtained.

#### The Association of Commonwealth Universities

THE annual report of the Council of the Association of Commonwealth Universities for the year ended July 31, 1964, records a membership of 139 institutions, of which 126 were universities, 9 university colleges and 4 approved institutions of higher education (Pp. 46. London: The Association of Commonwealth Universities, 1964). The work of the appointments department continued to increase, and the Association assisted in filling some 1,294 vacancies compared with 1,146 in 1962-63. Ninety-one advisory committees were set up at the request of universities to interview candidates in the United Kingdom; of appointments made by overseas universities reported to the Association during the year, about 140 were of candidates who had applied from Britain in response to the Association's announcements, 95 being in Australia. Through its work for the Commonwealth Scholarship and Fellowship plan in the United Kingdom, the Association was concerned with the administration of the Marshall scholarships, the Frank Knox Memorial fellowships, the Commonwealth University Interchange. It also continued to assist the Drapers' Company in its scholarship scheme to enable British schoolboys to take first degrees in some universities in Australia, Canada and New Zealand. The Association continued to act as the authority in the United Kingdom to attest the eligibility for admission to British universities of candidates seeking admission to French universities by virtue of examinations passed in Britain: 207 such attestations were issued during the year. A brief account of the work of the committee of Vice-chancellors and Principals of Universities of the United Kingdom is appended.

#### National Museum of Canada

THE National Museum of Canada Bulletin No. 202 (*Anthropological Series* No. 69) consists of a paper by

Asen Balikei on the development of basic socio-economic units in two Eskimo communities (Pp. x+114. Ottawa: Queen's Printer, 1964. 1.50 dollars). The author deals with the Arviligjaarmiut hunters of Pelly Bay and the Puvirnituirmiut trappers of East Hudson Bay, and considers that the cultural changes among the Eskimos described are essentially changes in socio-economic organization.

### Uganda Museum, Kampala

THE Report of the Trustees of the Uganda Museum for 1962 and 1963 records a period in which there have been numerous changes of personnel both among trustees and staff (Pp. 29. Kampala: Uganda Museum, 1964). It has also been a time of great advance in every sphere of the Museum's activities. The primary task has been to collect traditional material before it is too late, and to this end a body of informed collectors, asked to fill specific gaps in the collections, has been organized throughout Uganda. The impact of independence in 1962 gave a great impetus to pride in Uganda's past, and preservation is now seen to be a matter of urgency. The Kebu Association in Arua, for example, sent a large number of specimens to fill an almost complete gap in the collections. A large historical exhibition, *The Nile Quest*, was shown in 1962 as a contribution to the Nile Centenary Festival.

### Museum of Applied Arts and Sciences, Sydney

IN a modern and attractive format, the annual report of the Museum of Applied Arts and Sciences, Sydney, for the year ended December 31, 1963, records a total of more than 206,000 visitors, which is the highest figure reached within the eighty-three years of the Museum's existence (Pp. 28. Sydney: Museum of Applied Arts and Sciences, 1964). This result is due in no small measure to the high standard of recent exhibits, the intensified advertising programme and the increasing attention directed to the comfort and convenience of visitors. A major alteration during the period was the modernizing of the Museum's main entrance, thus relieving congestion at the front door and also creating a pleasing initial impact on visitors. The Planetarium and the 'Transparent Plastic Woman' continue to be very popular, and a major acquisition was the complete notebooks and papers of Lawrence Hargrave, Australia's aeronautical pioneer.

### New Reference Tools for Librarians

*New Reference Tools for Librarians*, compiled and edited by Hans Zell, contains some 2,000 entries of reference books, bibliographies and other publications on librarianship published in 1962-63 (Pp. v+232. Oxford: Robert Maxwell and Co., Ltd.; Long Island City, N.Y.: Maxwell International Inc., 1964. *Gratis*). It is intended to supplement standard reference works on the subject and does not include year books and annuals, annual reviews of progress or membership lists of learned societies and professional bodies. The emphasis is on British and American material and the scope is interpreted liberally to include material likely to be of service to librarians, and is not limited to material concerned with librarianship in the strict sense of the word. Entries are arranged under the Universal Decimal Classification.

The first supplement to *New Reference Tools for Librarians*, issued in March 1964, lists a further 600 new and forthcoming reference books, bibliographies and publications on librarianship, published in 1963-64, now including publishers' names. The second supplement includes a further 550 titles published in 1964, as well as some titles which appeared too late in 1964 for inclusion in previous catalogues. The emphasis is again on British and American publications (No. 1. Pp. 62. No. 2. Pp. 56. Oxford: Robert Maxwell and Co., Ltd.; Long Island City, N.Y.: Maxwell International Inc., 1964).

### Science Citation Index

A BOOKLET issued by the Institute for Scientific Information is intended to assist the scientist or librarian to use effectively the *Science Citation Index* for searching the literature (*Effective Use of the Science Citation Index: a Programmed Text*. Pp. 52. Philadelphia: Institute for Scientific Information, 1964). A general description of the *Index* is followed by explanations of its construction; the abbreviations of titles, authors' names and references which are used, and the characteristic features of the system, are demonstrated.

### Papermaking Research

THE British Paper and Board Industry Research Association at Kenley, Surrey, issues a quarterly journal called *What We Are Doing*. One section is confidential to members, but most of the remainder deals, usually in a general way, with the activities of the Association and contains book reviews and abstracts of scientific papers. Occasionally, for good measure, more detailed accounts of certain research activities of the Association are also released, the guiding principle being the extent to which they are of academic interest as distinct from technical importance. This is a wise policy, since it enables the outside world to assess the quality of some of the work being carried out by the Association. The June 1964 issue contains a typical example of this nature, dealing with the obviously important subject of the mechanism of rupture of paper under tension. An attempt is being made, and with some success, to correlate thin places in the paper with the path taken by the fracture propagated when a strip of paper breaks under tension. In the first example, the light transmitted by the paper through very small areas (approximately 0.23 mm<sup>2</sup>) was used to track the potential weak spots (that is, thin spots) in the paper. Afterwards  $\beta$ -radiography was used to determine the corresponding weights per unit area, an obviously more exact method of measuring a weak spot than from the thickness. A computer was then used to formulate the possible rupture paths, the input being obtained directly from the automatic scanning of the  $\beta$ -radiographs. The latest results are a striking justification of this method of forecasting the rupture propagation, and they have also demonstrated the overwhelming influence of abnormalities in the structure of the edge of the paper in initiating rupture. This work should eventually lead to a more exact understanding of the mechanism of fracture of non-homogeneous materials.

### A New Source of Petroleum

AFTER a quarter of a century's search for oil in the sheikdom of Abu Dhabi, on the Trucial coast of Arabia, aptly described as "a place of sand and sky and wide rolling horizons", pioneer efforts have been rewarded in the discovery of a new source of crude oil and development of a commercial field at Abu Dhabi, inland at a place called Murban, some miles from the sea. There is an offshore oilfield, about fifty miles out to sea, off the Abu Dhabi-Jebel Dhanna coast, which has been in production for two years or more, but the proving of the Murban oil area has been quite a different story. It is most uninviting territory, at least on surface, both from human and commercial points of view. "26,000 square miles of rolling sand dunes which imperceptibly merge into the wastes of Arabia's 'Empty Quarter' . . . noon temperatures of about 120 degrees Fahrenheit coupled with high humidity . . . sandstorms, shortage of water . . . difficulty of keeping food fresh and free from dust . . ."—these are the conditions under which the geologists, geophysicists and engineers had to work during many unrewarding years. Actually, the first well in the Murban area was drilled ten years ago, to 12,500 ft.; it yielded some oil and gas, but had to be abandoned for technical reasons; by unfortunate chance this well was located only about five miles north of the

now proved Murban field, but at the time this fact was unknown to the prospectors. A second well was completed five years ago which, together with the sub-surface information already provided by Murban No. 1, threw more light on the character of the underground formations in this area and prompted the placing and drilling of Murban No. 3; this well penetrated two oil-bearing formations and produced about 700 tons of oil per day on test. By October 1960, the results of these discovery wells were considered sufficiently encouraging to justify commercial production and export. On December 31, 1963, the 36,000 ton tanker *Esso Dublin* discharged the first cargo of Murban crude oil at the marine terminal of the Esso Petroleum Co.'s refinery at Milford Haven, Pembrokeshire. As an article in the *Esso Magazine* (13, No. 4; Autumn 1964) states: "The discovery of this new source of oil follows hard on the heels of the important discoveries in Libya and provides not only another sizeable addition to world proved reserves of oil, but also a further diversification of supply".

### Laboratory Guide to Ion Exchange

A USEFUL 42-page, illustrated manual entitled *Amberlite Ion Exchange Resins Laboratory Guide* was published in 1964 by the Rohm and Haas Co., Philadelphia, Pa., of which a brief summary appeared in *Rohm and Haas Reporter*, the periodical of the Company (22, 3; May-June 1964). Rohm and Haas pioneered development of ion-exchange technology in the United States and claims to be the first commercial organization in that country to produce synthetic, high-capacity ion-exchange resins on a large scale. The Company manufactures at present a complete range of laboratory and commercial ion exchange resins under the trademark 'Amberlite'. For laboratory use these resins are supplied in two different grades: chemically pure and analytical reagent. More than 30 different ion-exchange resins of varying porosity and particle-size are available in these grades, which are marketed by Mallinckrodt Chemical Works, St. Louis, Missouri. This manual describes "the many ways 'Amberlite' ion exchange resins may be used to eliminate difficult and time-consuming steps in laboratory work and explains how ion exchange operations are carried out. The manual emphasizes actual techniques for the use of ion exchange process in preparative and analytical work. . . . While primarily concerned with laboratory applications, the guide also reviews ways of using ion exchange resins in commercial processes". It is pointed out that these resins are exceptionally convenient to use; often, to make an analysis, the only equipment required is a glass column containing the resin beads. Separations can be performed more rapidly and determinations made more accurately by the analyst by this ion-exchange process than by the slower, often more cumbersome, methods of precipitation or crystallization. Copies of this guide can be obtained (gratis) from the Ion Exchange Department, Rohm and Haas Co., Philadelphia, Pa., 19105 (London subsidiary, Lemnig Chemicals Ltd., 26-28 Bedford Row, London, W.C.1).

### Microbiological Contamination of Food

CONTAMINATION of foods by micro-organisms does not constitute the hazard that it once did; however, new methods in processing and distributing foods are introducing new problems in food microbiology. A publication from the U.S. National Academy of Sciences—National Research Council, entitled *An Evaluation of Public Health Hazards from Microbiological Contamination of Foods*, examines the present position (Publication No. 1195. Food Protection Committee of the Food and Nutrition Board. Pp. vi + 64. Washington, D.C.: National Academy of Sciences—National Research Council, 1964. 2 dollars). It is concluded that it would be premature to adopt legal standards but recommends several steps which should be

taken to prepare the ground for their eventual adoption. It notes the increasing disparity between technical change and the level of efforts made to evaluate and control the health hazards with new products and processes. Comment is made on the poor reporting (in the United States) of the incidence of food-borne disease, the inconsistency of such reporting being shown by the fact that one State repeatedly reports 30-50 per cent of all outbreaks recorded by the Public Health Service. Definitions for microbiological specification, recommended microbiological limit and microbiological standard are proposed. The basic principles on which these criteria should be based are given. It is recommended that, before microbiological criteria for a food are adopted as an administrative device, standard methods of sampling and analysis of the foods in question should be agreed on. For this purpose, an organization similar to the Association of Official Agricultural Chemists should be formed in the field of food microbiology. Limits suggested by various workers for nine classes of foods are tabulated in an appendix together with 90 references to their source.

### Natural Radioactivity in Soils

THE dating of relics by radiocarbon analysis, which, in recent years, has come to be accepted as a most useful technique, is only one application of the measurement of the emissions from several radioactive elements. Obviously the principle might be used to estimate the weathering of soils from parent materials and the geological age of soils; moreover, the radioactivity of soils is affected by fall-out contamination from atomic explosions. A most useful review of present knowledge on this topic has been made by O. Talibudeen in *Soils and Fertilizers* (27, No. 5. Commonwealth Bureau of Soils, Rothamsted, 1964). He describes the properties of radioactive elements found in Nature and their contribution to the radioactivity of soils. About two-thirds of the total activity may be from potassium and thorium, and about 20 and 7 per cent from uranium and rubidium respectively. Carbon-14 contributes less than 0.5 per cent, and inorganic carbonate is more active than organic carbon of the same geological age, but carbonates may have isotopic exchange with atmospheric carbon dioxide, so that there are complications in the calculation of the age of organic residues in soil. The relative amounts of radionuclides in the soil are altered by such pedological processes as leaching, oxidation and reduction, and by the levels of sesquioxides, carbonates and organic matter, and the particle size distribution. The uranium in surface soils, for example, is related to their organic matter content, and the radium/uranium ratio is increased by leaching. The ratio of pairs of elements may help to assess the intensity of weathering in a soil profile, the thorium/uranium ratio being a more sensitive guide to leaching than the radium/uranium ratio. Short descriptions of the  $\alpha$ -,  $\beta$ - and  $\gamma$ -assays of radioactivity are given, with notes on corrections and interfering unstable nuclides. There are 9 tables of data and 2 figures of spectra, and a comprehensive list of references.

### Extraction of Forest Produce

THE British Forestry Commission Booklet No. 11 reviews extraction methods in use in Great Britain and also a few that have been tried but which have proved unsuccessful (*Extraction of Conifer Thinnings*. By R. E. Crowther. Pp. 74 + 15 plates. London: H.M.S.O., 1964. 5s. net). It is a timely publication because the extraction of forest produce is an important economic factor in forestry efficiency. Extraction is a costly business and it may account for 25-75 per cent of the total costs of production, excluding the cost of growing the trees. About two-thirds of the cut from State forests is made up of coniferous thinnings and at present some 40 million hoppus ft. of the latter are extracted in a year and the

amount is expected to rise to 85 million hoppus ft. in 1980. Much of this is destined for pulp and chipboard and thus much attention has been directed in recent years to increasing the efficiency of their extraction. The descriptions of the various extraction methods are based on experience and on the findings of the work study section, and supporting data are given in a series of tables. The general conclusions reached are that, of the seven types of extraction compared, the double drum winch is the best for both uphill and downhill hauls. Horse extraction is good for short distances downhill but not very efficient uphill, and under some conditions the wheeled tractor may be the cheapest method. So much importance is attached to the use of the Isachsen double-drum winch that Forestry Commission Booklet No. 12 is devoted to it (*Double Drum Winch Technique*. By R. E. Crowther and S. Forrester. Pp. 38+8 plates. London: H.M.S.O., 1964. 3s. net). This is a useful manual with clear explanations and good illustrations. It and its companion booklet are examples of concinnity.

### Royal Astronomical Society Awards

THE President and Council of the Royal Astronomical Society have made the following awards: *Gold Medals*, to Dr. G. M. Clemence of Yale University, in recognition of his applications of celestial mechanics to motions in the solar system and his fundamental contributions to the study of time and the system of astronomical constants; to Sir Edward Bullard of the University of Cambridge, for his pioneering work in geophysics and, in particular, his leadership in the field of studies of the geology of the ocean floor; *Eddington Medal*, jointly to Prof. R. V. Pound and Dr. G. A. Rebka of Harvard University, for their decisive experiment of measuring the gravitational red shift on the surface of the Earth through the methods of nuclear physics.

### Institute of Metals Awards

THE Council of the Institute of Metals has announced the following medal awards: *Institute of Metals (Platinum) Medal for 1965*, to Prof. A. H. Cottrell, in recognition of his services to the non-ferrous metal industries; *Rosenhain Medal for 1965*, to Mrs. M. K. McQuillan, in recognition of her contributions in the field of physical metallurgy; *W. H. A. Robertson Medal and Premium for 1964*, to Mr. D. Green, for his paper entitled "An Experimental High-speed Machine for the Practical Exploitation of Hydrostatic Extrusion" published in the *Journal of the Institute* (November 1964).

### University News:

DR. E. H. FROST-SMITH, research director with Stavely Industries, Ltd., has been appointed to the chair of electrical engineering.

#### Belfast

#### Birmingham

THE following appointments have been announced: *Lecturer*, Dr. D. A. Lihou (chemical engineering); Dr. K. C. Hooper (physiology); D. Tarin (pathology). *Research Fellow*, J. P. Barton (physics); C. A. T. Harnden (civil engineering); M. Landon (biochemistry); J. W. Dale (Senior Research Fellow in the Department of Experimental Pathology). The following titles have been conferred: *Reader*, Dr. S. A. Barker (carbohydrate chemistry); Dr. A. B. Foster (organic chemistry); Dr. G. J. Lawson (minerals engineering).

#### Bristol

DR. G. M. HUGHES has been appointed to the chair of zoology as from August 1, in succession to Prof. J. E. Harris. Dr. M. P. Banton has been appointed to the newly established chair of sociology as from August 1.

#### Cambridge

SIR EDWARD BULLARD, reader and head of the Department of Geodesy and Geophysics in the University of

Cambridge, has been appointed to the chair of geophysics at the University.

#### Lancaster

IN response to the recent appeal by the new University of Lancaster for funds to supplement its Government grants, Mullard, Ltd., has agreed to donate the sum of £10,000.

#### London

DR. H. R. V. ARNSTEIN, a member of the scientific staff of the Medical Research Council, has been appointed to the chair of biochemistry tenable at King's College. Dr. G. M. Jenkins, reader in mathematical statistics at the Imperial College of Science and Technology, has been appointed to the chair of statistics tenable at Queen Mary College. The following titles have been conferred: *Professor*, Dr. A. Ashmore (nuclear physics). *Reader*, Dr. D. F. Evans (inorganic chemistry); Dr. Marie B. Hall (history of science and technology).

### Announcements

THE name of the International Nickel Company (Mond), Ltd., has been changed to International Nickel, Ltd. This took effect as from January 1.

DR. VAN ZANDT WILLIAMS, president-elect of the Optical Society of America, has been appointed director of the American Institute of Physics with effect from April 1.

DR. H. K. CAMERON, chairman of the London Section of the Society of Chemical Industry, has been awarded the Lampitt Medal for 1965 by the Council of the Society of Chemical Industry.

DR. W. LANE-PETTER is relinquishing his position as director of the Laboratory Animals Centre, as from January 31, 1965, in order to become director of Carworth Europe, a subsidiary of Carworth Laboratories (U.S.A.).

MR. F. N. SUTHERLAND, deputy chairman and managing director of The Marconi Co., Ltd., has been appointed president of the Council of the Television Society as from January 1. Mr. Sutherland succeeds Sir Robert Fraser, who has held office for the past two years.

MR. F. D. OUTRIDGE was appointed director of the Council of the Scientific Instrument Manufacturers' Association, at their January meeting. He succeeds Capt. R. A. Villiers. Mr. Outridge joined the Association in 1961, and was appointed acting director in July 1964.

THE seventh session of the Welsh Soils Discussion Group on "Physical Aspects of Soil Fertility" will be held in Bangor on February 10. Further information can be obtained from Dr. A. H. Charles, Welsh Plant Breeding Station, Gogerddan, near Aberystwyth.

A SERIES of six evening lectures under the general title "Science, Industry and the State," organized by the Office of Health Economics, will be held at the Royal Society of Health during the first three months of 1965. Further information and forms of application for tickets can be obtained from the Director's Secretary, Office of Health Economics, 62 Brompton Road, London, S.W.3.

THREE lectures on "The Scientific Basis of Dentistry", arranged by the British Postgraduate Medical Federation, will be held at the Royal College of Surgeons on February 10, February 24 and March 10. The lectures, which are designed for research workers and specialists in training, will be as follows: "Science in Dentistry", by Prof. D. J. Anderson; "Electron Microscope Autoradiography", by Dr. S. R. Pele; "Histochemical Techniques in the Study of the Cellular Biology of Dental Tissues", by Dr. A. R. Ten Cate. Further information can be obtained from the British Postgraduate Medical Federation, 18 Guilford Street, London, W.C.1.

## CHEMICAL ENGINEERING STUDENTS

A SURVEY of students admitted to chemical engineering departments at universities and technical colleges in 1963 has been carried out by the Institution of Chemical Engineers in conjunction with Research Services, Ltd. \*. It covers all 19 institutions in the United Kingdom offering a full-time first-year degree course in chemical engineering, including students taking sandwich courses. Valid replies to the questionnaire totalled 931, and the 608 from chemical engineers represented an 89 per cent response. The survey indicated that while the difference between these groups of students was not as great as that between science and engineering students generally, students seeking a degree in chemical and mechanical engineering are of higher ability than engineering students in general. Chemical engineers originating from grammar or public schools showed no difference in ability, and while other schools held their own for the better students they provided a higher proportion of poorer students. The proportion of chemical engineers and chemists from public schools is lower than that of engineers or scientists in general.

Chemical engineers at grammar or public schools decide on their course at a considerably later stage than other students, only 8 per cent deciding on chemical engineering before taking the Ordinary Level examinations, compared with 31 per cent of chemists, while 44 per cent choose within the second or third year of their advanced work (22 per cent for chemists). Chemical engineers from other schools decide on their course even later. Motivation of careers is greater for students in technical colleges than for university students. More chemical engineers prefer to work in the field of design, construction, installation and plant maintenance than in other fields, most chemists electing for research and development work. The distribution of the intended field of work of students is often in marked contrast to that of the chartered membership of the corresponding professional engineering institution. Chemical engineers are better informed about the type of work they will be doing after leaving college and about the salary-levels to be expected than are other students, and 60 per cent would like to go abroad after completion of

study compared with 41 per cent of chemists, 'experience' being the motive most frequently given, with 'better opportunities for financial reward' a close second.

Most chemical engineers learned of the existence of their course from their chemistry teacher (28 per cent), general literature on careers (23 per cent) and college or university prospectuses (20 per cent). Relatives and friends were a source of information for 20 per cent of the chemical engineers from public schools, 14 per cent of those from grammar schools and 30 per cent of those from other schools. Almost half the chemists were given this information by their chemistry teacher. The Institution of Chemical Engineers was the second most frequently used single source for detailed information on the course, after college or university prospectuses, this information reaching 35 per cent of the public school boys, 29 per cent of grammar school boys and only 16 per cent of other school boys. The impact of the professional institution on mechanical engineers was only 6 per cent and on chemists only 2 per cent, but there was no indication that chemistry teachers or careers masters who do not teach chemistry were unable to supply detailed information on chemical engineering. For about half of all the students, sources connected with the school were decisive, chemical engineers quoting the chemistry teacher (16 per cent), literature from the Institution of Chemical Engineers (13 per cent) and (for public school boys only) people in the profession (23 per cent) as the most frequent single sources. Chemistry teachers decisively influenced 27 per cent of the chemists compared with 16 per cent of the chemical engineers, but the difference is unlikely to be due to careers masters who teach chemistry.

Of all the chemical engineers, 64 per cent seriously considered taking another course (1 in 3 considered taking chemistry and 1 in 7 a branch of engineering). Among the chemists 1 in 8 and among the mechanical engineers 1 in 28 considered chemical engineering. Of the chemical engineers who considered taking chemistry, 30 per cent decided against it because it offered fewer prospects for a career than chemical engineering. Less than 5 per cent of all chemical engineers could have been students who were refused admission to chemistry departments.

\* *The Institution of Chemical Engineers. The Choice of Chemical Engineering at University or Technical College: a Survey of Students Admitted in 1963.* Pp. vii + 53. (London: The Institution of Chemical Engineers, 1964.) 15s.

## THE ANIMAL VIRUS RESEARCH INSTITUTE, PIRBRIGHT

THE Animal Virus Research Institute is the new name for the Foot and Mouth Disease Research Institute at Pirbright, Surrey, and the report which has recently been published covers the years 1961-63\*. The Institute is still primarily concerned with the prevention and control of foot-and-mouth disease, and includes the World Reference Laboratory for this disease, but it is now intended that activities be extended to cover other virus diseases of animals as well. For this reason and because much of the research carried out at the Institute is of relevance to viruses in general a change of name was indicated.

The main theatres of operation for control of foot-and-mouth disease during the period reviewed were in South-West Africa, where extensive vaccination was carried out to control a large outbreak, and the Middle East, where the

African strain of virus became widespread in 1962. Such operations have naturally led to great demands on the Institute, particularly for live attenuated vaccine. The consequent problem of production has, however, been eased by a major development described in the report, namely the establishment of a co-operative project with the Wellcome Foundation. Under the new arrangements the Foundation will be responsible for production of live vaccine in a new building on the perimeter of the Institute.

This development has freed Institute staff and facilities for the pursuit of the proper function of research. Much effort has gone into methods for producing attenuated strains of virus suitable for immunization, and into studies on the safety of such strains when used in vaccines. The basic research which is reported may ultimately shed light on these and other problems. For example, genetic recombination has been achieved for the first time and may lead to detailed genetic analysis of foot-and-mouth disease virus. Viral replication is under investigation in

\* *The Animal Virus Research Institute, Pirbright. Report for the years 1961-1963.* Pp. 34. (Pirbright: The Animal Virus Research Institute, 1964.) 2s. 6d.

the biochemistry section. Immunity mechanisms are also being studied at a molecular level in the biophysics section.

One major difficulty in work on foot-and-mouth disease virus has been the lack of a suitable line of cells which can be continuously cultivated, and which is still sensitive to infection by the virus. The report describes how this difficulty has been overcome by the use of a diploid line of hamster fibroblasts. Cells of this line are highly sensitive, and are now used extensively for all types of research on the virus. The hamster cells are also proving to be suitable for mass culture and therefore for large-scale vaccine production.

It is gratifying to see from the report that the problem of disease security is continuing to attract the attention it deserves, and much of the building programme for the period under review has been concerned with improved isolation units and air-filtration equipment.

This will be the last report by Dr. I. A. Galloway, who has now retired after twenty-four years as director and who is succeeded by Dr. J. B. Brooksby. The wide scope and large scale of the activities described in the report are a particularly suitable record of the development which has taken place in the Institute under Dr. Galloway.

M. G. P. STOKER

## THE SHIRLEY INSTITUTE

THE idea of co-operative industrial research is well established in Britain, for there are no fewer than fifty research associations, each financed jointly by the industry concerned and the Department of Scientific and Industrial Research. In few instances has the work been more successful than in the case of the Cotton, Silk and Man-made Fibres Research Association, as is made abundantly clear in the 1964 annual report of the director, Dr. D. W. Hill\*, and by the stimulating exhibits which could be seen recently when the laboratories were open to members.

The Research Association, colloquially known as the "Shirley Institute", has established for itself a world-wide reputation based on its work on the constitution, reactivity and processing of cotton, but its activities now include work for the silk and the man-made fibres industries, particularly after the merger with the Rayon Research Association a few years ago. It is not possible in a short note even to summarize the wide range of topics at present being studied in the Association's laboratories, but two or three perhaps deserve special mention, because they illustrate the vision and foresight which have characterized the planning of the research programme and the close collaboration which exists between the Association's scientists and member firms.

One of these is the design of the automated system for producing yarn from raw cotton. The project has been developed to such an extent that mill trials are now in progress. As Dr. Hill states, "the introduction of automated processing is the one way in which this country

can compete with Eastern countries that have a large surplus of cheap labour". The system could be adapted to work in most modern mills, although considerable capital expense would be involved.

The Institute has for some time been carrying out research on the behaviour of fibres during stretching, and it was found that when fibres such as polyethylene are stretched they tend to split longitudinally. A similar phenomenon occurs when films are stretched, and from this observation has emerged a completely new method of producing fibres simply by stretching films under suitable conditions. Yarns can be spun from these fibres and the technique opens up many important possibilities.

Almost all the basic operations involved in converting fibres into finished cloth are being investigated in an attempt to obtain maximum efficiency in conventional techniques and to develop new ones, but an important aspect of the choice of topics is that the probable cost of each project has been assessed in the light of possible financial return. It is interesting that considerable stress is being laid on the production of stretch fabrics.

The work of the Institute is characterized by the careful balance between 'pure' and 'applied' research so that projects range from fundamental investigations to the solving of members' problems. During the past fifteen months covered by Dr. Hill's report, some 3,000 technical enquiries were dealt with. The scientific quality of the work at the Shirley Institute is high, and the present report shows that the Association is pursuing imaginative and profitable lines of research which will ensure that it continues to be one of the most highly regarded centres of fibre research. C. S. WHEWELL

\* Report of the Council and Statement of Accounts for the year ended March 31, 1964, presented at the forty-fifth annual general meeting of the Members of the Cotton, Silk and Man-made Fibres Research Association, held on Thursday, November 5, 1964.

## SCIENCE OF THE FABRICATION OF CERAMICS

THE meaning of the term 'ceramics' is to-day in a state of flux. Materials scientists tend to apply the term to any inorganic non-metallic material. Most of the workers in the field of ceramics—both the traditional and the new—feel that ceramics is a technological subject and that it is the fabrication process which brings the old and the new ceramics together. Basically the process may be described as the shaping of an article from a powder and its consolidation into a monolithic article by a high-temperature 'sintering' treatment. The scope of the meeting of the Basic Science Section of the British Ceramic Society, held at Brighton during October 12-14, 1964, was thus logically divided into three main sections: (1) preparation, characterization and properties of powders (chairman, Prof. J. White, University of Sheffield); (2) forming processes (chairman, Mr. A. Dinsdale, British Ceramic Research Association); (3) sintering and related processes (chairman, Dr. P. Murray, U.K. Atomic Energy Authority, Harwell). Some new and interesting processes

which did not fit into this scheme were dealt with in a fourth section entitled "Other Fabrication Routes" (chairman, Dr. J. Williams, U.K. Atomic Energy Authority, Harwell).

In order to acquaint the participants with recent developments and present-day thinking, the first three sections were each preceded by an introductory lecture. The first of these was given by J. Williams, who leads the very large ceramic team of the Metallurgy Division at Harwell. He emphasized the importance of the surface, since the driving force in the sintering process is the surface-free energy, and considered both its physics and its chemistry. Particle size and shape, and the deformation characteristics of powders, determined by their defect structure, were some of the points discussed.

The usual methods of characterization of a powder are by its particle size (for example, determined by optical and/or electron microscopy), its crystal size by X-ray line broadening, and surface area by the Brunauer-

Emmett-Teller adsorption method. In addition, B. R. Steele and his colleagues from the U.K. Atomic Energy Authority, Springfield, have used the measurement of gas permeability as a means of investigating the pore morphology of compacts. Although interpretation is difficult, because the pores form a three-dimensional interconnecting network of channels whereas flow is in a single direction, the breakdown of particle aggregates into fragments of the very small dimensions of the crystallites occurring during pressing has been examined by this method. Experiments on  $\text{UO}_2$  and  $\text{BeO}$  powders have shown a considerable difference in the bond strength between crystallites.

Many of the oxide powders used in ceramics are produced by thermal decomposition of hydroxides, followed by calcination. P. J. Anderson and his colleagues from Harwell showed, quoting as examples  $\text{MgO}$ ,  $\text{CaO}$  and  $\text{BeO}$ , how markedly the nature of the product of thermal decomposition could be affected by quite low partial pressures of  $\text{H}_2\text{O}$ . Water vapour affects the rate of nucleation of the oxide and enhances crystal growth during calcination (for example, at  $1,050^\circ\text{C}$ ). They doubted whether true vacuum conditions were obtained in many so-called 'vacuum-sintering' experiments because of the build-up of water vapour desorbed from the surface.

K. R. Poole, also of Harwell, discussed the statistics of mixing two or more powders. He showed that a single number that provided a measure of the difficulty of mixing, that is, the mean particle weight, could be deduced from a particle size distribution. Examples were given of how to calculate from this figure the random homogeneity of a mix, which makes it possible to decide whether it is practicable to improve a given mix by further mixing or whether size reduction of the components is necessary.

Comminution of particles is an important process that is little understood. J. Williams mentioned in the introductory lecture that only 5 per cent of the mechanical energy is used to create fresh surfaces, while the rest is converted into waste heat. Attempts to improve efficiency are thus important, and in view of the lack of a fundamental understanding the problem must at present be approached empirically for each material. M. G. Harwood (Mullard Radio Valve Co.) reported a very thorough investigation of the milling of iron oxide. Milling parameters (time, ball size, powder: water ratio, filling factor, dimensions and nature of lining of mill) were varied and their effect on surface area, reactivity, particle size and shape was examined. The following stages were observed: (1) 'de-agglomeration' with an increase of reactivity but not of surface area; (2) constant particle size but coating of the particles with some very fine ones which may arise from the wear of the ball or mill liner; (3) sudden break-up into fine components; (4) re-agglomeration or 'over-milling', resulting in decreased reactivity but not surface area.

Comminution by milling is only one particular method of obtaining fine powders. R. M. Glaister, of Standard Telecommunication Laboratories, Ltd., reported on a comparison of a variety of methods for preparing ultra-fine powders to be used in the sintering of magnetic ferrites to negligible porosity. Besides the conventional ball milling, he and his colleagues had examined chemical and electrolytic coprecipitation, treatment of metallic powders in steam, and a flame reaction process. The finest particles were obtained by decomposing a milled mixture of organic salts ( $0.25\text{ }\mu\text{m}$ ) and by flame reaction ( $0.7\text{ }\mu\text{m}$ ), although powders produced by electrolytic and chemical coprecipitation had much smaller crystallites than their apparent particle size of  $0.5\text{ }\mu\text{m}$  and  $1\text{ }\mu\text{m}$ , respectively. It will be interesting to see how these powders sinter.

A. L. Stuijts, from the Philips Research Laboratories, Eindhoven, gave the introductory lecture on "Forming Processes". After discussing briefly the peculiar rheo-

logical properties of powder-in-liquid suspensions, he dealt with the three most important traditional processes: slip casting, plastic forming (extrusion), and powder compaction. Much in this field is still an art rather than a science; there is no single unit or indeed any combination of properties by which one can assess the workability of a plastic mix and which might replace the 'potter's thumb'. While a certain amount of macroscopic data on compaction is available, little is known about the movement of powder in a die, about cohesion of powder and the properties required of a lubricant to decrease friction between powder and die and between the powder particles themselves. The three papers given in this section were all steps in the right direction, but much more work of this type is required. These seem to be research topics that could very well be tackled in the new technological universities.

Glass spheres and quartz, fluorite and baryte in various fractions between 20 and  $300\text{ }\mu\text{m}$  as model substances were used by A. Turba (Technische Hochschule, Karlsruhe) in his work on the behaviour of powders compacted in a die. The work required for compaction was determined by integration of an oscillogram of force versus displacement. To obtain distribution of porosity the compact was turned down on a lathe in twenty-five steps. Comminution of the original material was examined by comparing the particle size distribution before and after pressing. The effect of adsorbed gas and water molecules was also examined, but was found to play only a minor part. The paper by Capriz and Laratta on the "Extrusion of Non-Newtonian Bodies" was possibly too mathematical to be followed by most of the audience. However, it was highly relevant, as it dealt with pressure flow in a conical die and the behaviour of plastic materials during ram or auger extrusion.

C. F. Cooper and S. F. A. Miskin, of Morganite Research and Development, Ltd., presented new data on the kinetics of slip casting of  $\text{Al}_2\text{O}_3$ . The build-up of the cast was observed by means of  $\gamma$ -ray absorption. Casting rates were observed for casting slips in the pH range 0.5-14. The cast thickness showed a parabolic dependence with time. The temperature dependence of casting and the effect of variations in viscosity of the suspending fluid showed that the process was controlled by the rate of permeation of water through the cast layer.

Recent ideas on sintering were surveyed by Prof. White, an early exponent of the plastic flow theory, in his introductory lecture to the third section. The early stages of sintering, as demonstrated by the neck growth between two spheres, are now fairly well understood, and matter transport is generally believed to be due to volume diffusion. The later stages of sintering, leading to a pore-free material like 'Lucalox', are much less well understood, but it is well established that firing atmosphere and small additions, for example  $\text{MgO}$  in the case of  $\text{Al}_2\text{O}_3$ , can have a pronounced effect. A full understanding of the mechanism of the 'grain growth inhibitor' seems the most important problem still to be solved.

Work on material transport during the sintering of compacts of  $\text{ThO}_2$  and  $\text{CaO}$  was reported by C. S. Morgan (Oak Ridge National Laboratory). He and his colleagues suggested that the initial sintering was primarily by dislocation movement. D. W. Budworth's (University of Sheffield) experiments on the sintering of sodium chloride pointed towards the danger of the too ready acceptance of model experiments which proposed an evaporation-condensation sintering mechanism which is said not to lead to shrinkage. His work with A. Ammar has demonstrated that as much as 19 per cent shrinkage after 30 h sintering at  $740^\circ\text{C}$  on a powder compact of  $53\text{ }\mu\text{m}$  particles.

The sintering of fine alumina powders ( $0.1\text{--}1\text{ }\mu\text{m}$ ) in air and argon was examined by N. C. Kothari, of the Danish Atomic Energy Research Establishment. He concluded that bulk diffusion was the principal mechanism

of material transport. The effect of atmosphere on the density was much smaller than that observed by E. D. Macklen and P. Johns (Standard Telecommunications Laboratories) on manganese-zinc ferrites.

T. Vasilos presented a review paper covering a wide range of theoretical and practical aspects of hot-pressing. Some of the results obtained by him and his co-author, R. M. Spriggs, at the laboratories of the Avco Corporation, Massachusetts, were very impressive indeed; for example, hot-pressing MgO *in vacuo* has resulted in a highly transparent material of theoretical density. The use of non-graphite dies and high pressures had given a fully densified material of small grain size. In fact, it appeared that the grain size was essentially the same as the particle size of the powder. Unfortunately, these fine-grained high-density materials were weaker than those with coarser grains, contrary to expectation. It was suggested that densification in these materials when formed at ultra-high pressures was entirely the result of plastic deformation and therefore only a weak bond was formed between particles. In general, the authors supported diffusion as the main mechanism of densification. The many questions from the participants showed the great interest in the new techniques, which used pressures up to 750,000 lb./in.<sup>2</sup>.

The densification of kaolin and mixtures of silica and alumina at much more moderate pressures (50,000 lb./in.<sup>2</sup>) and temperatures up to 900° C using dies of heat-resisting metals was discussed by T. G. Carruthers and T. A. Wheat (University of Leeds). Mullite formed at surprisingly low temperatures, and the parts played by chemically bound and physically adsorbed water were discussed.

Two of the papers, by J. F. MacDowell (Corning Glassworks, U.S.A.) and by P. W. McMillan and G. Partridge (English Electric), in the final section, "Other Fabrication Routes", were concerned with the production of dense polycrystalline materials by controlled nucleation of glasses.

The final paper, presented by A. G. Thomas, of the Plessey Research Laboratories, described the coating of very small spheres of UO<sub>2</sub> with Al<sub>2</sub>O<sub>3</sub> in a fluidized bed by the hydrolysis of AlCl<sub>3</sub>.

The meeting, which was organized by Dr. D. T. Livey, of the Metallurgy Division, Harwell, was, in my opinion, an unqualified success. It had a balanced programme which offered something to every worker in the field of ceramics. It was attended by 150 people, of whom half were members of the Society and half guests. The papers presented at this meeting will be published in a separate volume of the *Proceedings of the British Ceramic Society*.

P. POPPER

## NATURE OF ELECTRON EQUILIBRIUM IN HETEROGENEOUS SOLIDS AND THE PROPOSED ELECTRON ENERGY DISTRIBUTION IN DEGENERATE *p-n* JUNCTIONS\*

By PROF. M. A. MELEHY

University of Connecticut, Storrs

IT is well known that the concept of Fermi-level constitutes one of the most important fundamentals of the modern electron theory of solids. According to quantum statistics<sup>1</sup>, this level may be defined to be the highest energy-level occupied by electrons at absolute zero. At higher temperatures, the Fermi-level may be defined to be that for which the probability of occupation by electrons is one-half.

A universally accepted idea, called the 'fundamental principle of statistical mechanics', states that if two or more different solid crystals are brought together to form a contact, then in thermal equilibrium the Fermi-level is constant at every point of the assembly, regardless of the distribution of the electron and hole concentration. Thus, for example, in thermal equilibrium, the Fermi-level in a *p-n* junction is constant at every point of the crystal including the transition region and even the metal ohmic contacts. A statement of this 'principle' may be found in many standard text-books on different subjects such as statistical mechanics, thermo-electricity, and the theory of *p-n* junctions in semiconductors.

It has recently been shown<sup>2</sup> that for the important general class of non-degenerate semiconductors, the validity of the 'principle' described above could not be justified. For simplicity, the argument has been deliberately confined to non-degenerate semiconductors, since for that class of solids, as is well known, the Fermi-Dirac statistics approach the Maxwell-Boltzmann statistics. Thus, electrons and holes may be considered as boltzmann gases, and the well-known classical gas laws may be applied.

This article shows that the arguments and conclusions concerning the electron equilibrium and its energy distribution, arrived at for non-degenerate *p-n* junctions, do

follow from more general new and established quantum-mechanical and quantum-statistical laws. These laws are applicable to heterogeneous metals and semiconductors in general.

In the first two sections we shall review and develop the concepts needed for examining the validity of the 'principle' mentioned earlier. We shall show in section (3) that the basic difficulties with this 'principle' can be directly traced to the conventional mechanism of electron equilibrium in heterogeneous solids. The proposed mechanism of equilibrium and resulting mathematical relations described in section (4) will provide, among other conditions, a basis for some proposed fundamental postulates in quantum statistics later stated in section (5). The postulates pertain to the quantum-mechanical formulation of the concepts of vapour pressure, and the particle diffusion force, all for electron and hole fermion gases in solids. From these postulates and the well-established physics of solids, a number of fundamental relations will be derived. These include the diffusion potentials<sup>3,4</sup>, the diffusion-mobility generalized relationship and, most importantly, the particle diffusion force Fermi-level relationship and the electron energy distribution in degenerate *p-n* junctions with wide and thin transition regions.

From time to time we shall refer to some of the material presented in ref. 2. It is therefore suggested that the reader may do well to acquaint himself thoroughly with the relatively straightforward classical treatment in that reference before attempting to understand the more involved quantum-mechanical theory presented here.

The term *solids* whenever used is meant to include *metals* and *semiconductors*. The latter may be degenerate or otherwise. For all these classes of solids, we shall assume that the volume energy density of quantum states is parabolic.

\* Supported in part by the University of Connecticut Research Foundation.

In many instances we shall describe a solid as being *heterogeneous*. This will consist of three basic classes. The first is characterized by a spatial variation of the atomic structure. The second by a nearly uniform atomic structure but with a spatial variation of the density or type of impurities. The third by a spatially varying atomic structure as well as density or type of impurities. Examples of the first case include metal-metal, and metal-semiconductor interfaces. Examples of the second include various kinds of  $p$ - $n$  junctions, degenerate or otherwise. Examples of the third are heterojunctions in semiconductors, degenerate or otherwise.

As will become apparent later, the concept of average energy for electrons or holes plays an important part in formulating and understanding the new mechanism of electron equilibrium and the development of the general theory to be presented here. Thus we shall first begin with analysing this important concept.

### (1) Average Energy of Conduction Electrons in Solid Crystals

In this section a general expression will be derived for the average energy of electrons  $\langle \epsilon \rangle$  in the conduction band of a metal or semiconductor. We shall see that  $\langle \epsilon \rangle$  will depend on temperature alone in the case of non-degenerate semiconductors. For metals and degenerate semiconductors,  $\langle \epsilon \rangle$  will depend mostly on the Fermi-level  $\epsilon_f$ .

The average energy  $\langle \epsilon \rangle$  may be defined to be given by:

$$\langle \epsilon \rangle = (1/n) \int_0^\infty \epsilon g(\epsilon) F(\epsilon, \epsilon_f) d\epsilon \quad (1)$$

where  $\epsilon$  is any energy-level in the conduction band measured from its bottom, and  $\epsilon_f$  is the Fermi-level. The latter is considered positive if it lies in the conduction band. The other quantities in equation (1) are described as follows:

$$g(\epsilon) = C_n \epsilon^{1/2} \quad (2)$$

$$F(\epsilon, \epsilon_f) = \{1 + \exp[(\epsilon - \epsilon_f)/kT]\}^{-1} \quad (3)$$

$$n = \int_0^\infty g(\epsilon) F(\epsilon, \epsilon_f) d\epsilon \quad (4)$$

Here  $g(\epsilon)$  is the volume energy density of quantum states in the conduction band and is assumed to be parabolic<sup>6</sup>,  $C_n$  is a constant which depends on the electron effective mass, and Planck's constant. The function  $F(\epsilon, \epsilon_f)$  is the Fermi-Dirac<sup>6,7</sup> probability distribution function,  $k$  is Boltzmann's constant and  $T$  is the absolute temperature. The quantity  $n$  represents the volume concentration of electrons in the conduction band.

In order to make use of the tables of the Fermi-Dirac functions, computed by McDougall and Stoner<sup>8</sup>, to evaluate numerically  $\langle \epsilon \rangle$ , we must introduce in equation (1) two variable transformations. These are:

$$\zeta = \epsilon/kT \quad (5)$$

and:

$$\eta = \epsilon_f/kT \quad (6)$$

In view of all the preceding equations, equation (1) may be written as:

$$\langle \epsilon \rangle = (3/2)kT \rho_\epsilon(\eta) \quad (7)$$

where:

$$\rho_\epsilon(\eta) = (2/3)F_{3/2}(\eta)/F_{1/2}(\eta) \quad (8)$$

and:

$$F_{\kappa}(\eta) = \int_0^\infty \zeta^\kappa d\zeta / [1 + \exp(\zeta - \eta)] \quad (9)$$

Fig. 1 represents the coefficient  $\rho_\epsilon$  as a function of  $\eta = \epsilon_f/kT$ . The quantity  $\rho_\epsilon(\eta)$  may be interpreted as the ratio of the average energy of each conduction electron to the classical average thermal energy  $(3/2)kT$ . It is interesting to notice that  $\rho_\epsilon$  is very nearly 1 whenever  $\epsilon_f$  is below the bottom of the conduction band. The reader will recognize this case to correspond to non-degenerate

Fig. 1. Dependence on  $\eta = (\epsilon_f/kT)$  of: (a) ratio  $\rho_\epsilon$  of the average energy  $\langle \epsilon \rangle$  of an electron in the conduction band to  $(3/2)kT$ ; (b) ratio  $\rho_{ea}$  of  $(D/\mu)$  to  $(kT/q)$ . The Fermi-level  $\epsilon_f$  is measured from the bottom of the conduction band

$n$ -type semiconductors, or to  $p$ -type semiconductors of any degree of degeneracy or non-degeneracy. The coefficient increases rather rapidly for  $\eta > 0$  and can be shown<sup>9</sup> to approach  $0.4\eta$  asymptotically. This limit is closely reached for strongly degenerate  $n$ -type semiconductors and metals, for which  $\langle \epsilon \rangle \approx 0.6 \epsilon_f$ .

By a similar treatment, it can be shown that the plot of  $\rho_\epsilon(\eta)$  of Fig. 1 may also represent a  $p$ -type semiconductor crystal. For this case the point  $\eta = 0$  would represent the Fermi-level coinciding with the top of the valence-band band, and  $\eta > 0$  would correspond to a degenerate crystal, while  $\eta < 0$  corresponds to a non-degenerate crystal.

It is interesting to notice that for any semiconductor crystal, degenerate or otherwise, the average energy of minority carriers in thermal equilibrium is  $(3/2)kT$  within the respective band, regardless of the carrier concentration. For majority carriers, this conclusion will be true only for a non-degenerate semiconductor crystal.

### (2) Electron Forces and Electron Currents in Heterogeneous Solids

In this section we shall derive from a phenomenological argument some general fundamental relations between the density of electron current in a solid and the forces exerted on the electrons in the conduction band by one or more processes. These relations are important for a clear understanding of the basic questions to be raised and the proposed answers.

Let us consider a solid crystal in which the conduction is only caused by an electrostatic field  $\vec{E}$ , which may be uniform or otherwise. At any point  $P$  in the crystal, the electron current density  $\vec{J}$  may be expressed as:

$$\vec{J} = \mu n(q\vec{E}) \quad (10)$$

Here  $q$  is the magnitude of the electron charge, and  $n$  and  $\mu$  are the electron volume concentration and mobility at point  $P$ , respectively.

Equation (10) may now be interpreted in a more general way. The quantity  $(-q\vec{E})$  represents the average electrostatic force  $\vec{f}_e$  acting on the electron. This force is undoubtedly responsible for the current  $\vec{J}$  under the conditions assumed here. The nature of this force, however, is not really important in so far as the magnitude

and direction of the current  $\vec{J}$ . This will mean that if the conduction electrons were acted on at  $P$  by an equal force  $\vec{f}$  of different nature, then the current  $\vec{J}$  would remain indeed unchanged, provided that  $(\mu n)$  continued to be the same. Therefore, we may now predict the current density  $\vec{J}$  at a point  $P$ , if we know the net average force  $\vec{f}$  acting on each electron at that point. This force may be caused by one or more processes. In general, we may write:

$$\vec{J} = -\mu n \vec{f} \quad (11)$$

and say that  $\vec{f}$  is the resultant of all the average forces exerted by all the processes on the electron at  $P$ .

It should be noticed that equation (11) has been derived without any restriction on the position of the Fermi-level. Hence it may be assumed that the equation is valid for all the solids of interest here.

By a similar argument, it can be reasoned that for a  $p$ -type semiconductor, except for a different sign, an equation identical to that of equation (11) may be obtained.

It can now be shown that equation (11) would lead to a familiar important relationship, usually stated for non-degenerate semiconductors. In such crystals, if the conduction is caused by the diffusion and electrostatic processes, then in view of equation (11), we may write:

$$\vec{J} = -\mu n (\vec{f}_d + \vec{f}_e) \quad (12)$$

where  $\vec{f}_d$  and  $\vec{f}_e$  are the average forces exerted on the electron due to the diffusion and drift processes, respectively.

It has been shown<sup>2</sup> from a pure thermodynamic argument that for a classical ideal boltzon gas, under isothermal conditions:

$$\vec{f}_d = -(kT/n)\nabla n \quad (13)$$

and:

$$D/\mu = kT/q \quad (14)$$

Here  $D$  and  $\mu$  are the diffusion constant and mobility, respectively, for the electron gas considered. Recalling that  $\vec{f}_e = -q\vec{E}$ , then from equations (12), (13) and (14), we have:

$$\vec{J} = qD\nabla n + qn\mu\vec{E} \quad (15)$$

which is a well-known relation. Equation (15) has been used in ref. 2 in discussing the inconsistencies of the conventional energy distribution in non-degenerate  $p$ - $n$  junctions. It will now be noticed that equation (15) is derived on the basis of equation (11) and the ideal gas laws. This will explain why it is justifiable to apply the ideal gas laws to non-degenerate semiconductors, as has been exclusively done in ref. 2.

### (3) Critique of the Conventional Mechanism of Electron Equilibrium in Heterogeneous Solids

We shall next discuss some fundamentally objectionable consequences of the conventional concept of electron equilibrium. The latter is well known to lead supposedly to the familiar 'principle' of constant Fermi-level in heterogeneous solids if they are in thermal equilibrium.

Under thermal equilibrium conditions, it is generally assumed that at every point in a heterogeneous solid, the diffusion current  $\vec{J}_d$  and drift current  $\vec{J}_e$  are equal and opposite, so that:

$$\vec{J} = \vec{J}_e + \vec{J}_d = 0 \quad (16)$$

We shall call this condition *flow equilibrium* to distinguish it from the alternative one to be discussed in the next section.

At first glance, equation (16) appears to be valid, for it seems that if this equation were not satisfied, a current would flow under thermal equilibrium, which clearly would not be possible. Despite this apparent validity of equation (16), the flow equilibrium it describes implies inevitably fundamental subtle but serious contradictions. To explain this statement, consider equation (11), which in view of equation (16) may be written as:

$$\vec{J} = -\mu n \vec{f} = 0 \quad (17)$$

where  $\vec{f}$  is the net average force acting on the electron due to the processes of diffusion and drift. Recalling that equation (17) is supposed to hold at every point in the transition region, and that  $\mu \neq 0$ , and  $n \neq 0$ , then it follows that  $\vec{f} = 0$ .

Thus it can be stated that *the conventional flow equilibrium clearly leads to the conclusion that in thermal equilibrium an electron crossing any solid-solid interface would do so at constant energy*. Some direct consequences of that statement are:

(a) A denial of the existence of the well-known Peltier effect<sup>10</sup>, which only exists because of the possibility that an electron crossing an interface can change its energy, so that the interface thermal energy has to change in such a way as to satisfy the requirements of the first law of thermodynamics<sup>11</sup>.

(b) In the case of a non-degenerate  $p$ - $n$  junction, as shown in section (1) the average majority and minority electron energy is  $(3/2)kT$  above the bottom of the conduction bands everywhere in the crystal. Hence, in thermal equilibrium, the conclusion of a constant electron energy everywhere in the transition region will mean that the conduction bands throughout the crystal should line up. This conclusion, of course, contradicts the conventional concept of the energy diagram which for this simple case would be as represented in Fig. 2. It is clear in that figure that an electron crossing the junction from the  $n$ - to the  $p$ -region, under thermal equilibrium conditions, would gain an amount of energy equal to  $(kT)\ln(n_n/n_p)$ .

It will now be recalled that we have shown earlier that the flow equilibrium leads to the constant electron energy everywhere in a heterogeneous solid crystal. Yet the conventional theory uses the same assumption and concludes that substantial changes do occur in the electron energy under the same conditions. A legitimate question of particular interest at this point would be: how has the conventional theory reasoned on the basis of flow equilibrium the conventional conclusions? We shall

Fig. 2. Conventional electron energy band diagram for a non-degenerate  $p$ - $n$  junction in thermal equilibrium

next summarize and interpret the conventional steps in terms of the electron forces.

The conventional theory begins with assuming equation (16), and (in view of equation (11)) proceeds to consider that at every point of a heterogeneous solid in thermal equilibrium:

$$\vec{J}_e + \vec{J}_d = -\mu n(\vec{f}_e + \vec{f}_d) = 0 \quad (18)$$

Here  $(\vec{f}_e + \vec{f}_d)$  represents the total force acting on the electron at any point due to drift and diffusion. To avoid using the unfortunate consequence of equation

(18) that  $(\vec{f}_e + \vec{f}_d)$  should indeed everywhere be zero, and so would have to be the net change of electron energy, the common procedure is to change the appearance of  $(\vec{f}_e + \vec{f}_d) = 0$  to:

$$\vec{f}_d = -\vec{f}_e \quad (19)$$

It must be noticed here that neither  $\vec{f}_e$  nor  $\vec{f}_d$  represents the total force acting on the electron at any point. Now integrating each side of equation (19) with respect to the distance  $x$ , across, for example, a transition region of width  $w$  in a  $p$ - $n$  junction, provides of course a non-zero answer. This answer has been interpreted to be the built-in potential, considered to be electrostatic in nature, and invariably treated likewise. The integral will be:

$$-\int_0^w \vec{f}_e \cdot d\vec{x} = \int_0^w \vec{f}_d \cdot d\vec{x} \quad (20)$$

It might interest the reader to see further that for a non-degenerate  $p$ - $n$  junction, if we substitute  $\vec{f}_d = (-kT/n)(dn/dx)$ , which has been derived<sup>2</sup> on the basis of the ideal gas laws, equation (20) will become:

$$\begin{aligned} \psi_0 &= -\int_0^w \vec{f}_d \cdot d\vec{x} = \int_0^w \vec{f}_e \cdot d\vec{x} \\ &= -(kT) \int_{n_n}^{n_p} dn/n = (kT) \ln(n_n/n_p) \end{aligned} \quad (21)$$

where  $w$  is the width of the transition region, and  $\psi_0$  is the conventional 'built-in potential'. This result can be shown to require that the Fermi-level should be constant throughout the crystal. For example, it may be explained on the basis of equation (21) by substituting for  $n_n$  and  $n_p$  their values expressed in terms of  $(\epsilon_c - \epsilon_f)$  and  $(\epsilon_f - \epsilon_v)$ , respectively. Here  $\epsilon_c$  is the lowest energy-level in the conduction band of the  $n$ -region, and  $\epsilon_v$  is the highest energy-level in the valence-band of the  $p$ -region. The detailed steps may be found in many standard books on  $p$ - $n$  junction theory.

The reader will now appreciate that the quantity  $\psi_0$ , calculated in equation (21), is not really the total built-in potential. On the contrary, according to equations (19) and (21),  $\psi_0$  represents only the magnitude of either the diffusion or the electrostatic potential. Since according to the assumption of flow equilibrium the two potentials are supposed to be equal and opposite, they should have indeed added up to zero. To avoid facing the conflict of this result with the implications of the Peltier effect, the conventional theory appears as though it has chosen to consider one of the potentials and ignore the existence of the other. Then the chosen potential has been defined to be the electrostatic potential. What has helped conceal these fundamental inconsistencies seems to be the lack of a clear understanding of the nature and properties of the particle diffusion force. So the diffusion process has conventionally been thought to be associated with only a flow, but not a force. It may now be appreciated why it would be essential to understand how the electron equilibrium can be established in a manner compatible with the Peltier effect and other well-established laws of Nature. These fundamental questions will be dealt with in the coming sections.

#### (4) Proposed Mechanism of Electron Equilibrium in Heterogeneous Solids

In section (3) it has been seen how the assumption of flow equilibrium of electrons in solids would present a fundamental conflict with the existence of the Peltier effect. This conflict has arisen over the fact that when it is recognized that the diffusion process exerts an average force on each electron, the assumption of flow equilibrium implies that an electron crossing any heterogeneous region of a solid would do so at constant energy. If we now are permitted to accept as a matter of fact the existence of the Peltier effect, we must inevitably state that: *under thermal equilibrium conditions, the net average force acting on each conduction electron in a heterogeneous solid is not necessarily zero at every point.*

At first glance, this statement appears as though it might not be valid, for it may seem to lead to a net flow of electrons under thermal equilibrium conditions. Such a flow, of course, would be impossible. As will be shown shortly, this statement is only paradoxical, as it does not necessarily require such a current under thermal equilibrium.

To explain this point and its consequences, consider a heterogeneous solid forming a closed loop. Let the whole body be in thermal equilibrium. If the net average force  $\vec{f}$  exerted on each electron is not necessarily zero, then we must conclude that the average value of  $\vec{f}$  around any closed loop  $C$  within the solid must vanish; that is the line integral of  $\vec{f}$  around any closed loop is zero, or:

$$\oint_C \vec{f} \cdot d\vec{s} = 0 \quad (22)$$

If we now assume that  $\vec{f}$  is caused by the electrostatic and diffusion processes, we may replace  $\vec{f}$  by  $(\vec{f}_e + \vec{f}_d)$ . Therefore, equation (22) may be written as:

$$\oint_C (\vec{f}_e + \vec{f}_d) \cdot d\vec{s} = \oint_C \vec{f}_e \cdot d\vec{s} + \oint_C \vec{f}_d \cdot d\vec{s} = 0 \quad (23)$$

According to the well-known laws of electrostatics, the line integral of the electrostatic field  $\vec{E}$ , and  $\vec{f}_e = -q\vec{E}$ , around any closed loop must vanish<sup>12</sup>. Thus, equation (23) reduces to:

$$\oint_C \vec{f}_d \cdot d\vec{s} = 0 \quad (24)$$

In view of Stokes's theorem<sup>13</sup>, we may express the condition for equilibrium described by equation (24) in the microscopic form:

$$\nabla \times \vec{f}_d = 0 \quad (25)$$

which would be valid at any point.

We may summarize the preceding discussions and results in the following statement: *A necessary and sufficient condition for equilibrium of electrons in solids under the action of diffusion alone is that the line integral of the electron diffusion force around any closed loop is zero. This also means that the curl of this force must vanish at every point. Thus the electron diffusion force constitutes a conservative field.*

Equations similar to (24) and (25) are well known to hold for electrostatic and gravitational fields, which are all conservative.

Since each of the possible processes in a heterogeneous solid is associated with a conservative force field, we may state the familiar principle of detailed balancing<sup>14,15</sup> of statistical mechanics in a more detailed way as follows: *Under thermal equilibrium conditions, at any point in a heterogeneous solid, for every electron which is crossing a given area in one direction per unit time due to each process, there is another which is crossing it in the opposite direction.*

Thus, it can clearly be seen that the principle of detailed balancing holds true for all the processes combined.

As an interesting application of equation (24), we shall discuss the equilibrium of the diffusion process in a non-degenerate semiconductor crystal on the basis of the classical formulation of the particle diffusion force of ref. 2. For simplicity let the crystal geometry resemble a ring consisting of any finite number of regions, such as three. Each region has a uniform electron concentration designated as  $n_1$ ,  $n_2$  and  $n_3$ . It is evident that in thermal equilibrium, an electron moving along any closed loop  $C$  within the crystal would be acted on by a non-vanishing

diffusion force  $\vec{f}_d$  only in the transition regions. In this event  $\vec{f}_d$  will be as given by equation (2) of ref. 2. Thus, the average value of  $\vec{f}_d$  over the closed path  $C$  will be proportional to:

$$\oint_C \vec{f}_d \cdot d\vec{s} = kT[\ln(n_1/n_2) + \ln(n_2/n_3) + \ln(n_3/n_1)] = 0 \quad (26)$$

Hence the condition described by equation (24) is satisfied, regardless of the number of different regions in the crystal. We may therefore conclude that the particle diffusion force in its classical form, as defined in ref. 2, does meet the requirements of the new concept of equilibrium.

### (5) Quantum-statistical Formulation of the Particle Diffusion Force

It has been shown that, from a purely thermodynamic argument<sup>2</sup>, the *particle diffusion force* for an ideal classical gas would be  $\vec{f}_d = (-k/n)\nabla(nT)$ . We have used this answer to calculate the *diffusion potentials* in any isothermal non-degenerate  $p$ - $n$  junction. For this class of semiconductors, as is well known, the electrons (and holes) behave very nearly like ideal boltzon gases.

If we now wish to calculate the diffusion potentials in any isothermal heterogeneous solid in general, we must first seek a more general formulation for  $\vec{f}_d$ . This formulation must fulfil the following requirements: (1) preserve the nature of  $\vec{f}_d$ ; (2) obey the laws of quantum mechanics; (3) allow the electrons to behave as fermion gases; (4) tend to the classical formulation, if the fermion gas tends to be a boltzon gas; and (5) lead to a force field, which is conservative, so that equations (24) or (25) are satisfied. We shall see that all these requirements are fulfilled by means of an established law of quantum statistics and three proposed ones. These laws are to be stated and discussed next.

*Vapour pressure of a fermion gas:* This physical quantity is generally defined<sup>16</sup> to be given by:

$$p = (2/3)n\langle\epsilon\rangle \quad (27)$$

Here  $n$  is the volume concentration of the gas particles and  $\langle\epsilon\rangle$  is the average energy of each particle.

Equation (27) is essentially an extension of that derived for a classical gas (ideal or otherwise), which is usually stated as:  $p = mn\langle v^2 \rangle / 3$ . Here  $m$  and  $v$  are the gas particle mass and velocity, respectively, and  $m\langle v^2 \rangle / 2$  has been interpreted to be  $\langle\epsilon\rangle$ .

*Postulate I:* The vapour pressure and the diffusion of a fermion gas constitute different formulations of the same process. This will mean that both formulations are mutually inclusive, so that one uniquely determines the other.

This postulate is again an extension of the classical properties of vapour pressure and diffusion discussed in ref. 2.

*Postulate II:* The preceding postulate suggests the existence of a mathematical link between the concepts of diffusion and vapour pressure. This link may be

reasonably expected to be the *particle diffusion force*. For a fermion gas we postulate it to be given by:

$$\vec{f}_d = - (1/n)\nabla p \quad (28)$$

It will be noticed that equation (28) is a three-dimensional form of equation (1) of ref. 2. The latter equation has been derived for a classical gas, ideal or otherwise. So we merely postulate here that equation (28) holds beyond a classical gas.

*Postulate III:* If there is more than one kind of gas, then equation (27) and the preceding postulates will

still hold, provided that the variables  $\vec{f}_d$ ,  $\epsilon$ ,  $p$  and  $n$  are considered to be for any one kind of gas. Thus, for example, equations (27) and (28) may be applied to either electrons or holes in semiconductors, provided that the respective variable mathematically exists within a closed domain in which the potentials are to be computed.

### (6) Equilibrium Relationship between the Particle Diffusion Force and the Fermi-level in Isothermal Heterogeneous Solids

In this section, we shall derive a fundamental relationship between the (average) particle diffusion force  $\vec{f}_d$  at any point in an isothermal heterogeneous solid and the Fermi-level  $\epsilon_f$  at that point. We shall then discuss the result, which will be of considerable importance in determining the electron energy distribution in any isothermal heterogeneous solid. The basic assumption we shall make here is that the average energy of the electron at every point of interest in the solid corresponds to the electron-lattice equilibrium value at that point. This will mean that the electron has a sufficiently large number of collisions in the immediate neighbourhood of every point of interest so that any energy it has above or below the local equilibrium value is transferred almost entirely to the lattice. Examples, for which this assumption holds, are what we shall call *wide-junction p-n diodes*. These  $p$ - $n$  junctions may be degenerate or non-degenerate. Further discussion of these examples, together with others called *thin-junction p-n diodes*, for which this assumption is not fulfilled, may be found in sections 8 and 9.

In order to relate  $\vec{f}_d$  to  $\epsilon_f$ , at any point of an isothermal heterogeneous solid satisfying the assumption stated here, consider equations (27) and (28), from which it follows that:

$$\vec{f}_d = - (2/3n)\nabla(n\langle\epsilon\rangle) \quad (29)$$

Substituting equation (1) into equation (29), we get:

$$\vec{f}_d = - (2/3n)\nabla\left\{\int_0^\infty \epsilon g(\epsilon) F(\epsilon, \epsilon_f) d\epsilon\right\} \quad (30)$$

Here  $g(\epsilon)$  and  $F(\epsilon, \epsilon_f)$  are as given by equations (2) and (3). Notice that  $n$  and  $\epsilon_f$  in equation (30) are functions of position, whereas  $\epsilon$  is not so. Therefore, equation (30), after some manipulation, will yield:

$$\vec{f}_d = (2C_n/3n)(\nabla\epsilon_f)\int_0^\infty \epsilon^{3/2} \frac{d}{d\epsilon} \{1 + \exp[(\epsilon - \epsilon_f)/kT]\}^{-1} d\epsilon \quad (31)$$

Integrating equation (31) by parts, we get:

$$\vec{f}_d = - (C_n/n)(\nabla\epsilon_f)\int_0^\infty \epsilon^{1/2} \{1 + \exp[(\epsilon - \epsilon_f)/kT]\}^{-1} d\epsilon \quad (32)$$

In view of equations (2), (3) and (4), equation (32) will reduce to:

$$\vec{f}_d = - \nabla\epsilon_f \quad (33)$$

where  $\epsilon_f$  is measured from the bottom of the conduction band.

It must be remembered here that the nature of  $\vec{f}_a$  is not electrostatic. Rather,  $\vec{f}_a$  is entirely caused by the diffusion process, which is generally due to electron-phonon, electron-impurity<sup>17</sup> and possibly electron-electron interactions. This is why  $\vec{f}_a$  after all has been invariably termed the (average) *particle diffusion force*. At any point, this force, according to equation (33), depends only on the gradient of the Fermi-level. Since the curl of any gradient is zero, we may conclude that:

$$\nabla \times \vec{f}_a = 0 \quad (34)$$

Again from equation (33), it follows that the line integral of  $\vec{f}_a$  between any two points depends on the end points rather than the path. Thus  $\vec{f}_a$  constitutes a conservative field, and satisfies the necessary and sufficient conditions for the new mechanism of equilibrium (see equations (24) and (25)).

At this point, the striking significance of equation (33) may not be fully apparent. As an illustration, in the next three sections some particularly important consequences of this fundamental relationship will be discussed.

### (7) The Generalized Diffusion-mobility Relationship in Degenerate Solids

In this section we shall derive a general relationship between the mobility  $\mu$  and the diffusion constant  $D$  for electrons in solids. To do so, we consider the classical definition of  $D$  to be given by Fick's law:  $\vec{J}_a = qD\nabla n$  (ref. 18). Here  $\vec{J}_a$  signifies the electron current density associated with diffusion. By virtue of equation (11) and Fick's law, we may define  $D$  in terms of the particle diffusion force  $\vec{f}_a$  at any point in a solid by:

$$\vec{f}_a = -\vec{J}_a/(\mu n) = -q(D/\mu)(\nabla n)/n \quad (35)$$

Substituting equation (33) into equation (35), and solving for  $(D/\mu)$ , we get:

$$D/\mu = (n/q)(\nabla \epsilon_f)/\nabla n \quad (36)$$

In view of equations (2), (3), (4), (5), (6), (9) and (36), it can be shown that:

$$D/\mu = (kT/q)\rho_a \quad (37)$$

where:

$$\rho_a = [F_{1/2}(\eta)]/\{dF_{1/2}(\eta)/d\eta\} \quad (38)$$

The dependence of the coefficient  $\rho_a$  on the Fermi-level is plotted in Fig. 1. The curve has been computed from the tables of the Fermi-Dirac functions<sup>8</sup>. It can be shown<sup>18</sup> that  $\rho_a$  tends asymptotically to  $(2/3)\eta$ . Thus for metals and strongly degenerate semiconductors, the diffusion-mobility relationship becomes:

$$(D/\mu) \cong (2/3)\epsilon_f/q \quad (39)$$

It is interesting to see that for  $\eta < 0$ , that is, for any non-degenerate semiconductor,  $\rho_a$  approaches 1. Consequently the ratio  $(D/\mu)$  also will approach  $(kT/q)$ , which is the Einstein diffusion-mobility relationship originally derived for ideal boltzon gases.

### (8) Proposed Energy Band Diagrams for Wide-junction Degenerate p-n Diodes

In this section some of the basic general laws established earlier will be applied to determine the energy band diagrams for wide-junction p-n diodes.

Before treating the p-n junction problem, it might be pedagogically desirable to review briefly the important basic properties of the *electron diffusion force*  $\vec{f}_a$ . First,

it must be emphasized that the nature of  $\vec{f}_a$  is not electrostatic. More specifically,  $\vec{f}_a$  is due to the diffusion process, which is the inevitable consequence of the random interaction of a spatially varying density of electron population with the atomic lattice structure. We have furthermore shown that  $\vec{f}_a$ , like the electrostatic electron force  $\vec{f}_e$ , must constitute a conservative field. Thus, it is self-evident that if an electron moves within a solid between any two points, then, regardless of the path, in thermal equilibrium the average work done on the electron due to the processes of diffusion and drift will be:

$$W_{ab} = \int_a^b (\vec{f}_a + \vec{f}_e) \cdot d\vec{s} = \int_a^b \vec{f}_a \cdot d\vec{s} + \int_a^b \vec{f}_e \cdot d\vec{s} \quad (40)$$

It is also self-evident that equation (40) would still hold if thermal equilibrium is disturbed by, for example, a net flow of electrons, provided that the flow does not introduce new processes unaccounted for, such as the electron-hole generation or recombination in semiconductors.

Another relation of considerable importance is described by equation (33). According to this equation, within a heterogeneous solid:

$$\int_a^b \vec{f}_a \cdot d\vec{s} = - \int_a^b \nabla \epsilon_f \cdot d\vec{s} = \epsilon_f(a) - \epsilon_f(b) \quad (41)$$

Here  $\epsilon_f$  is always referred to the bottom of the conduction band. It should be recalled that equation (33), and hence equation (41), are based on the assumption that the electron has sufficient collisions with the lattice atoms in the immediate neighbourhood of points  $a$  and  $b$ , so that its energy may be considered equal to the electron-lattice equilibrium values at either of the two points.

Next, equations (40), (41) and other relations will be used to determine the electron energy distribution in a degenerate wide-junction p-n diode. For such a crystal, let the spatial variation of the Fermi-level  $\epsilon_f$  (referred to the bottom of the conduction band) be as shown in Fig. 3a. In thermal equilibrium, an electron crossing the junction, from the  $n$ - to the  $p$ -region, according to equation (41), will gain from the diffusion process alone an amount of energy equal to the difference between the Fermi-levels at either side of the junction. This energy will be designated as  $\phi_0$  and will be considered to be a positive quantity.

Now consider Fig. 3b, which, as will be shown shortly, represents the energy band diagram corresponding to the process of diffusion alone. The amount of energy  $\phi_0$  must then represent the change in the average electron energy as it crosses the junction from one end to the other. The average values of electron energy in the  $n$ - and  $p$ -region, however, are:  $(3/2)kT\rho_n$  and  $(3/2)kT\rho_p$ , respectively (section 1). Thus from the geometry of Fig. 3b, the bottom of the conduction bands in the  $n$ - and  $p$ -regions must be separated by an amount of energy equal to  $(\phi_0 + \delta)$ , where:

$$\delta = (3/2)kT(\rho_n - 1) \quad (42)$$

Again from the geometry of Fig. 3b, this will mean that in thermal equilibrium the Fermi-level in the  $p$ -region must be above that of the  $n$ -region by an amount of energy equal to  $\delta$ .

The quantity  $\delta$  is not insignificant for strongly degenerate p-n junctions and some metal-semiconductor contacts. This may be seen by referring to section (1) in which we have observed that, for large values of  $\eta$ , the factor  $\rho_n$  tends to 0.4 ( $\epsilon_f/kT$ ). Hence, for strongly degenerate p-n junctions and some metal-semiconductor contacts, in the limit:

$$\delta = 0.6 \epsilon_f \quad (43)$$

Here  $\epsilon_f$  is the energy between the Fermi-level and the bottom of the conduction band.

Now let us consider the electrostatic junction built-in potential associated with the force  $\vec{f}_e$  acting on an electron as it crosses the transition region. This will be done first

Fig. 3. (a) Spatial variation (referred to the bottom of the conduction band) of the Fermi-level  $\epsilon_f$  and average electron energy  $\langle \epsilon \rangle$  in a degenerate wide-junction p-n diode. Also energy band diagrams for this crystal when it is: (b) in thermal equilibrium and only the diffusion process is accounted for; (c) in thermal equilibrium and both the diffusion and drift processes are accounted for; (d) forward biased and both processes are accounted for. The complete potential  $(\phi_0 + \delta - \psi_0)$  in case (c) has been arbitrarily chosen positive

for a crystal in thermal equilibrium. It should be noticed that in the transition region, the electron forces  $f_d$  and  $f_e$  are always in opposite directions. Since  $f_d$  has been defined in equations (40) and (41) as a positive quantity, to be consistent, we must consider  $f_e$  to be negative. Furthermore, the energy term in equation (40) contributed by  $f_e$  must also be negative. Therefore, we may define the line integral of  $f_e$  across the entire transition region to be  $(-\psi_0)$ , where  $\psi_0$  is positive. Thus the composite built-in potential across the transition region (referred to the conduction bands) will be  $(\phi_0 + \delta - \psi_0)$  as shown in Fig. 3c. So, from the geometry, it can be seen that in thermal equilibrium, the Fermi-levels across the transition region must be displaced by an amount of energy equal to  $(\psi_0 - \delta)$ .

The changes in the energy band diagrams, if thermal equilibrium is disturbed by forward biasing will now be discussed. We shall only treat the case in which no carrier generation or recombination would occur in the transition region.

Under forward-biasing conditions, if minority electrons are injected in a sufficiently long p-region, there will be an excess-charge zone within that region where recombination takes place. It can be shown<sup>20</sup> that the average energy gained by an electron in that zone due to the diffusion process is at most  $kT$ , provided that the injected minority carriers do not reach degenerate proportions. Thus, for convenience, in most practical cases we may completely neglect this quantity.

Consider now the p-n junction, its ohmic contacts and the battery supplying the power. Let it be assumed that the current in the circuit is sufficiently small so that the distribution of electrons in the ohmic contacts does not deviate from thermal equilibrium, and the Joule losses are negligible everywhere. Since the electron energy must be conserved as it goes round the circuit, then the junction built-in potential must change from its thermal-equilibrium value of  $(\phi_0 + \delta - \psi_0)$  to  $(\phi_0 + \delta - \psi_0 - v)$ . Here  $v$  is the forward applied voltage. This change in the junction potential has been arrived at on the basis that, on forward biasing, the electron gains  $v$  electron volts from the battery. Since the diffusion and electrostatic potentials in the ohmic contacts have been assumed to remain constant on forward biasing, the junction potential must then change in such a way as to satisfy the law of conservation of energy. Fig. 3d represents the complete energy distribution in a forward-biased p-n junction.

It is interesting to notice here that the energy band diagram of Fig. 3d and that of Fig. 4c of ref. 2 are compatible. The reason for this is that for non-degenerate semiconductor crystals, according to Fig. 1 and equation (42), the quantity  $\delta = 0$ . Therefore the two diagrams mentioned here become identical.

It should be emphasized that the electrostatic potential  $\psi$  must always satisfy at every point of the transition region the fundamental relation:

$$\nabla^2 \psi = -q(p' - n + N_d - N_a)/\epsilon_0 \quad (44)$$

Here  $p'$  is the density of holes and  $N_d$  and  $N_a$  are the concentrations of the ionized donor and acceptor atoms, respectively, and  $\epsilon_0$  is the dielectric constant.

It should be noticed that the change  $v$  in the built-in junction potential from its thermal equilibrium value is partly electrostatic and partly due to diffusion. The electrostatic part should add up with  $\psi_0$  to make  $\psi$ , which must satisfy the laws of electrostatics as expressed by equation (44). The diffusion part of  $v$  should add up with  $(\phi_0 + \delta)$  to make  $(\phi_0 + \delta)$  which must obey the quantum statistical laws of diffusion. How  $v$  will be divided between the diffusion and electrostatic potentials will depend largely on the situation considered. Further discussion of this point as applied to the injection theory in non-degenerate p-n junctions may be found in section 4 of ref. 2.

(9). Proposed Energy Band Diagrams for Thin-junction Degenerate  $p$ - $n$  Diodes

In section (8), we have seen the part which the  $f_d$  and  $\epsilon_f$  equilibrium relationship plays in determining the electron energy distribution in degenerate wide-junction  $p$ - $n$  diodes. As mentioned earlier, in such  $p$ - $n$  junctions, there are sufficient electron-lattice collisions in the neighbourhood of every point of interest, so that the electron energy corresponds to the equilibrium values at these points.

The object of this section is to investigate the electron energy distribution in an important different class of  $p$ - $n$  junctions. This class is characterized by having space-charge regions so thin that the electron-lattice equilibrium cannot be established within these regions.

It should be recalled that according to section 4, under thermal equilibrium or otherwise,  $f_d$  and  $f_e$  would not necessarily be equal at every point. The validity of this statement may be most clearly seen in Fig. 4. This figure represents the energy band diagrams for a thin-junction  $p$ - $n$  diode, under thermal equilibrium and forward biasing.

To understand these diagrams and how they have been arrived at, consider an electron crossing from the  $n$ - to the  $p$ -region. Let the crystal be first in thermal equilibrium. As the electron crosses the thin space-charge layer, it will be acted on by an opposing electrostatic force ( $-|f_e|$ ). The line integral of this force will transfer to the electron an amount of energy ( $-\psi_0$ ), where  $\psi_0$  is positive. The electrostatic potential  $\psi_0$  must satisfy equation (44).

A simple model is now to be described from which the spatial variation of the diffusion potential in the non-equilibrium region may be determined. It is self-evident that in that region, the electron cannot experience  $f_d$  at all before it makes its first collision. Since collisions are random events, we must only be concerned with the statistical average of these events and their consequences. As the electron passes point A (Fig. 4a) and moves to the right, collisions are bound to occur. These will give rise to an average transfer of energy from the lattice to the electron. When sufficient collisions have happened, the electron energy will attain its equilibrium value. Reaching equilibrium, however, will require time. Since the electron velocity is finite, a certain distance is required in which nearly complete interaction between the electron and the lattice may be accomplished.

To calculate the spatial dependence of  $\phi$  in the junction non-equilibrium diffusion region, consider an electron moving to the right at point A of Fig. 4a. For simplicity, let the width  $w_e$  of the space-charge region be negligibly small. At point  $x = 0$ , before any collisions have occurred, clearly  $\phi = 0$ . At any positive  $x$ , the change in the diffusion potential  $d\phi$  across  $dx$  will be proportional to  $dx$  and to the difference between the equilibrium value of  $\phi$ ; namely  $(\phi_0 + \delta)$ , and  $\phi(x)$ . Thus we may write:

$$d\phi = (\phi_0 + \delta - \phi)dx/L_i \quad (45)$$

Here  $L_i$  may be defined as the *electron-lattice interaction length*. Conceivably this quantity will depend on the mean free path and on the fraction of the energy difference between the lattice and the electron transferred on the average to the latter during each collision. For simplicity, consider  $L_i$  to be constant. This is particularly justified if the impurity concentration outside the space-charge region is constant, as is generally assumed to be the case. Solution of equation (45), subject to the conditions that  $\phi(0) = 0$ , and  $\phi(\infty) = (\phi_0 + \delta)$ , will be:

$$\phi(x) = (\phi_0 + \delta)[1 - \exp(-x/L_i)] \quad (46)$$

Equation (46) is represented in Fig. 4a. In that figure, for simplicity,  $L_i$  has been chosen to be much larger than  $w_e$ .

Let us next consider the energy band diagram corresponding to forward biasing. This is represented in Fig.

Fig. 4. Complete electron energy band diagrams for a degenerate thin-junction  $p$ - $n$  diode: (a) in thermal equilibrium; (b) under forward biasing

4b. As explained in the previous section, the net change in the composite potential between points A and C must be  $(\phi_0 + \delta - \psi_0 - v)$ . This value follows from the principle of conservation of energy. The new quantity  $v$  must be split into two parts. One must be due to diffusion and the other must be electrostatic. The positive diffusion part  $v_d$  must subtract from  $(\phi_0 + \delta)$  to make  $\phi = (\phi_0 + \delta - v_d)$ , while the electrostatic part  $(v - v_d)$  must add up with  $(\psi_0)$  to make  $\psi = (\psi_0 + v - v_d)$ . Now the quantity  $\psi$  must satisfy equation (44).

It should be noticed that the composite built-in potential across the entire transition region (referred to the conduction bands) is:

$$(\phi_0 + \delta - v_d) - (\psi_0 + v - v_d) = \phi_0 + \delta - \psi_0 - v \quad (47)$$

As expected, the right-hand side of equation (47) is identical with the result obtained for wide-junction  $p$ - $n$  diodes.

The energy band diagrams discussed in this section are believed to be particularly important for all  $p$ - $n$  junctions in which the tunnelling process takes place. It can be shown that these diagrams predict the new mechanism of tunnelling-induced injection of minority carriers<sup>21</sup>. This particular mechanism pertains to the process we believe to be occurring, for example, in  $p$ - $n$  junctions in direct<sup>22</sup>

semiconductors, for which high-efficiency emission of infra-red radiation and the laser action have been reported<sup>23-25</sup>.

For tunnelling non-degenerate  $p$ - $n$  junctions, it can be seen that the diagrams of Fig. 4 would remain substantially the same, except that  $\delta$  may be considered zero.

### (10) Summary and Conclusion

The main object of this article has been to: (1) develop new general equilibrium laws, which electrons should obey in heterogeneous degenerate and non-degenerate solids; (2) apply these general laws to determine new electron energy diagrams for degenerate  $p$ - $n$  junctions, with wide and thin transition regions.

Without loss of generality, the processes considered are mainly diffusion and drift. It has been shown that the mechanism of electron thermal equilibrium in solids cannot be correctly described on the basis of current or current tendencies as generally assumed. Rather, a valid description of this mechanism requires use of the concepts of (average) particle drift and diffusion forces  $f_e$  and  $f_d$ , respectively. The latter force has been formulated quantum statistically for any fermion gas. The new laws require that at every point in a heterogeneous solid in

thermal equilibrium only curl  $(\vec{f}_e + \vec{f}_d) = 0$ . This is in contrast with the conventional assumption, which,

if expressed in terms of these forces, would be  $(\vec{f}_e + \vec{f}_d) = 0$ . The latter condition would not be compatible with the existence of the Peltier effect, although conceivably it would hold for neutral gases. An implication of the new condition is that the electron force  $f_d$ , as is well known for  $f_e$ , constitutes a conservative force field in any heterogeneous solid.

We have furthermore shown that, contrary to general belief, the Fermi-level is indeed far from being constant at various points of any heterogeneous solid in thermal equilibrium. On the basis of the new laws, the relative values of this level have been evaluated for any solid-solid interface. This made it possible to determine new energy

diagrams for degenerate  $p$ - $n$  junctions, under thermal equilibrium and forward-biasing conditions.

In almost all the natural and life sciences, one may expect to find numerous processes and phenomena involving the transport in heterogeneous substances of electrons and/or other charged gases. Thus, as it now seems to be the case for solid-solid interfaces, it might be advisable to re-examine the validity of every foundation, principle and theory pertaining to such processes and phenomena wherever they may be.

## EFFECT OF TENSILE LOADING ON HYDROGEN MOVEMENT IN STEEL

By STEVE EISNER

Martin Co., Denver, Colorado

THE rate of entry of hydrogen into a steel-walled 6 V6 vacuum tube has been used as an index for hydrogen concentration in steel. The device acts as an ionization gauge. The tube ion current is changed by the presence of hydrogen gas in the tube. This is detected and measured with appropriate electronic equipment.

The Lawrence hydrogen gauge was used to determine the relative rate of hydrogen migration through the walls of a 1010 steel 6 V6 tube when it was placed under tensile loading. The tube was stripped of paint and nickel plate, then hydrogen-charged by making it a cathode in a 1 per cent NaCN and 1 per cent NaOH solution. Current density was 1 amp/ft.<sup>2</sup> for 5 min. It was found that the initial ion current decay rate varied with different tubes (an indication of non-uniform gettering ability of commercial 6 V6 tubes). For this reason, only qualitative effects were anticipated. The charging was carried out in all cases by immersing the tube in the charging solution up to a distance 1/2 in. from the base of the tube.

The tube characteristics were: (1) shell wall, 1010 aluminium-killed steel 0.06 in. thick; (2) tube vacuum— $10^{-8}$  mm mercury; (3) tube type, 6 V6 tetrode; (4) tube shell temperature, 50° C.

The tubes were loaded, and the ion current was recorded before hydrogen charging.

The uncharged tube always gave a slight sharp instantaneous peak on the first loading and afterward showed little or no response. The ion current in all cases shows the gradual drop with time that is due to the gettering action of the tube.

The assembly shown in Fig. 1 was fabricated for tensile loading. The 6 V6 tube was fastened to the jig with low-temperature indium solder to prevent damaging of the tube by overheating. The tubes were loaded, and ion current was recorded before hydrogen charging. A pure tensile load was applied after the tube was hydrogen-charged. The maximum applied load was varied from 0 to 12,000 lb./in.<sup>2</sup>. The rate of loading and unloading was 0.01 in./in./min.

The hydrogen-charged tube was loaded in tension and unloaded with 25 lb. (500 lb./in.<sup>2</sup>) increments at each loading.

No detectable change in ion current occurred until a 300-lb. (6,000 lb./in.<sup>2</sup>) load was applied. After this loading level, an increase in ion current always occurred on loading. On unloading, the ion current returned to

Fig. 1. Assembly used for tensile loading of 6V6 steel-walled tube. The tube is immersed in the hydrogen-charging solution up to the flat base plate. It is then rinsed and dried and loaded in a tensile testing machine

the normal decay curve. Typical loading and unloading curves at loads of 520 (10,380 lb./in.<sup>2</sup>) to 600 lb. (12,000 lb./in.<sup>2</sup>) are shown in Fig. 2. At loads above 450 lb. (9,000 lb./in.<sup>2</sup>), the solder fastening the tube to the jig began to creep. These curves show that the ion current is increased when a tensile load is applied and decreases as it is removed. They show that the amount of increase is greater as the applied load is greater.

The sharp instantaneous peak on tension loading of hydrogen-free tubes looks very similar to the peak obtained on tapping or striking the tube, and is probably the same effect even though the mechanical load is, in our experiments, a pulling effect.

Moving dislocations can carry an atmosphere of impurities along with them. The smaller the impurity atom is, the more easily this can happen. Hydrogen atoms would be easily moved through a metal lattice by moving dislocations. Frank<sup>1</sup>, using a mass spectrometer, detected a rapid increase in hydrogen emitted from a hydrogen-charged steel bar when it was bent in the mass spectro-

Fig. 2. Ion current versus time recording for a hydrogen-charged tube in tensile loading. Note. 1, Rate of loading is held constant. 2, Tensile load is increased by 25-lb. increments. 3, Gradual drop of ion current with time is due to gettering

meter. His explanation was that the dislocations moved on application of a bending load, carrying their hydrogen atmospheres to the surface where the hydrogen escaped and was registered.

In our experiments, an increase of ion current (hydrogen pressure) in the tube occurs when the tensile load is applied. This levels off as the load is held constant and drops to the normal value when the load is released. For the hydrogen pressure to remain constant (excluding normal gettering effects), a continuous new supply of hydrogen must be carried to the surface. A single rapid spurt of dislocations would cause an increase in ion current and then a rapid decay to the same level as in the unloaded state. This obviously does not occur. Although the load level of 6,000 lb./in.<sup>2</sup> is below the apparent elastic limit of the metal, some dislocations probably move to the surface. The sustained load may keep a relatively constant number of dislocations moving to the surface with their accompanying atmospheres of hydrogen. At present, this appears to be the most logical interpretation.

## FACTORS INFLUENCING BIOMAGNETIC ENVIRONMENTS DURING THE SOLAR CYCLE

By W. C. LEVENGOOD

University of Michigan, Institute of Science and Technology, Ann Arbor

**D**URING the eleven-year period of the solar cycle there are pronounced and somewhat systematic variations in the flux of both solar and cosmic ray particles reaching the Earth's surface. These two environmental parameters are inversely related; that is, as the

solar activity increases the cosmic ray flux decreases. This article will not be directly concerned, however, with the mechanisms causing these changes in radiation-levels, but instead it examines some of their effects on living organisms subjected to magnetic field environments.

Fig. 1. Sketch of test magnet with culture bottles in position

The reported findings centre around the reproductive responses of the fruit fly, *Drosophila melanogaster*, and involve a continuation of an investigation which demonstrated an inverse relationship between solar flare activity and the progeny yields of flies grown in magnetic fields<sup>1</sup>. This relationship was found just following the 1958 maximum in the solar cycle when the solar activity was still high. The inverse correlations were believed to be caused by the influence of the magnetic fields on incoming ionizing particles which increase during periods of active solar flares. Although it was suggested that these effects were due to the influence of a magnetic field on the path of charged particles, many questions remained to be answered concerning the subtle relationships between the magnetic field conditions and the changing environmental parameters.

Presented also are speculations concerning the mechanism producing the experimentally observed trends. Emphatically it is not intended that these hypotheses are the only explanations for the observed effects; however, in many cases the variations in the results are consistent with known or inferred fluctuations in geophysical or astrophysical conditions. In the formulation of the suggested relationships between reproductive responses and radiation effects, summarized data from the International Geophysical Year have been utilized. In one section, for example, satellite results are presented which indicate a possible influence of the outer Van Allen radiation belt on the reproductive response effects.

With only a few exceptions the experimental procedure was as previously given<sup>1</sup>: culture bottles designated as *N* and *S* were placed on opposite poles of permanent magnets with pole faces 4.5 cm<sup>2</sup> and an 8-cm separation. This experimental arrangement provides two magnetic fields similar in strength but with opposing orientation. The field strengths decrease from the pole regions and a measure of the divergence of flux is indicated in Fig. 1, showing a pair of bottles in position. The culture bottles were 5 cm in diameter and 11.5 cm high; medium (cornmeal-molasses type with propionic acid mould inhibitor) was placed in the bottom to a depth of about 2.5 cm. The laboratory temperature was 22° ± 2° C, and both barometric pressure and relative humidity were monitored.

Each magnet was placed in one of four geomagnetic orientations, and this designated orientation was maintained throughout an entire series of generation matings. For example, east (*N*)—west (*S*) means the *N* pole was oriented geomagnetic east and the *S* pole geomagnetic

west. The *N* and *S* culture bottles were compared as pairs in each generation, and after the *F*<sub>1</sub> repeated filial generation crosses were made using six adult pairs removed from the preceding *F* generation. The parents were left ten days in the bottles. Countings were made over an 8-day interval, starting with the day the new generation flies were seen. Cultures hereafter designated as 'controls' were grown out of the magnetic fields, and all cultures were initiated, as well as removed and counted, on the same dates.

As in the previous investigations, the environmental parameters were averaged over a 72-h period covering the day before, the day of, and the day after the matings in the new culture. During this specific 72-h period in the life-cycle, these organisms disclose a high sensitivity to environmental changes.

Values for solar flare activity may disclose day-to-day fluctuations of several orders of magnitude. Therefore, it has been found advantageous<sup>1</sup> to use the factor *S'*<sub>*F*</sub> given by:

$$S'_F = \log (S_F + 1) \quad (1)$$

where *S*<sub>*F*</sub> is the daily value issued by the High Altitude Observatory, Boulder, Colorado<sup>2</sup>. The (*S*<sub>*F*</sub> + 1) factor not only provides logarithmic comparisons but also allows on a logarithmic basis a data point for the occasional sequence of zero values for *S*<sub>*F*</sub> over the 72-h period of interest.

Cosmic ray data were obtained through the courtesy of Prof. J. A. Simpson, Enrico Fermi Institute of Nuclear Studies, University of Chicago. These were reduced by a constant factor to give more convenient numbers in the analyses; the *C'*<sub>*R*</sub> or 'reduced factor' is:

$$C'_R = (C_R - 2,000) \times 10^{-3} \quad (2)$$

where *C*<sub>*R*</sub> is the bi-hourly count of neutron flux corrected for barometric pressure.

The previously used statistical correlation coefficient *r* gives a measure of the degree of linear correlation in the data being compared. If the correlation is only approximately linear and follows some higher order function one cannot evaluate or examine the relationship by simply determining the correlation coefficient. The present work was therefore examined using a method of grouped or cell frequency data analysis<sup>3</sup>. A dependent variable such as progeny yield (*F*<sub>*t*</sub>) was grouped according to variations in an environmental parameter or independent variable. Progeny data which were chronologically the same and grown on magnets with the same orientations were grouped according to interval changes in a given environmental parameter; for example, let us say in the interval change of *C'*<sub>*R*</sub> from 0.95 to 0.96 all the progeny (total counts designated as — *F*<sub>*t*</sub>) from generations located within this interval were tabulated and an average taken. This system of grouping may be shown by the general expression:

$$\bar{M}_1 = \frac{\sum [(F_t)_A \dots (F_t)_B]}{n}; \quad \bar{M}_2 = \frac{\sum [(F_t)_C \dots (F_t)_D]}{n}; \quad (3)$$

where  $\bar{M}_1$  is the mean value of the environmental parameter and *n* is the number of progeny generations in the interval [(*F*<sub>*t*</sub>)<sub>*A*</sub> ... (*F*<sub>*t*</sub>)<sub>*B*</sub>], etc. Intervals of  $\bar{M}$  were chosen so that generally at least four *F*<sub>*t*</sub> values were averaged. In many cases there were 10–20 progeny generations within the interval. If an  $\bar{M}$  interval contained less than four *F*<sub>*t*</sub> values the data were incorporated into the next nearest bracket of  $\bar{M}$  values. It appeared that over intervals containing 15–16 generations of flies the  $\bar{M}$  values disclosed sufficient variation to make this method of data analysis feasible. It should also be pointed out that the possibility of the variations in progeny with the  $\bar{M}$  values being caused by genetic drift is negligible. Each  $\bar{M}$  interval contained a selection of *F* generations which

Fig. 2. Grouped cosmic ray-progeny data for sixteen generations [east (N)-west (S) orientation], 1962 data

Fig. 3. Reproductive response in  $F_1$  generations grown out of field (removed from one magnet in series shown in Fig. 2)

depended on the level of the random fluctuations in the environmental parameter, and this greatly reduces the possibility of the trends being caused by a sequential change.

Within each frequency cell, data points are presented for the biomagnetic conditions  $N$  and  $S$  as well as the controls or  $C$  values. Since data points for each  $F$  generation in a test series correspond chronologically the differences between individual  $C$  and the  $N$  or  $S$  progeny generation points may be analysed using statistical comparisons of the population means within a given  $M$  cell. The standard deviation of the mean of the paired differences  $-\sigma_d$  is given by

$$\sigma_d = \left[ \frac{\sum (d_i - \bar{d})^2}{n(n-1)} \right]^{1/2} \quad (4)$$

where  $d_i$  represents the difference  $N_1 - C_1$  or  $S_1 - C_1$  depending on whether comparisons are being made between the  $N$  or  $S$  pole data. The value of  $\bar{d}$  is the mean of the differences and  $n$  the number of pairs in the  $M$  interval. The  $t$  test for significance is then calculated from:

$$t_N = \frac{(\bar{N} - \bar{C})}{\sigma_d} \text{ or } t_S = \frac{(\bar{S} - \bar{C})}{\sigma_d} \quad (5)$$

The values of  $t_N$  or  $t_S$  were compared with the values in a  $t$ -table of significant differences<sup>4</sup>. The discussions of the presence or lack of significance of specific data in the following sections are based on this method of analysis.

Results from grouped data are given for the most recent tests as well as a re-examination of experiments conducted over the past several years. By examining all this information the period of coverage extends from the initial test series when the solar activity was still moderately high into the present condition of the "quiet sun". The general approach is to examine the more recent tests (1962), then discuss results extending back towards the 1958 solar maximum. Finally, some of the perplexing aspects of the early environmental investigations are considered in the light of the recent findings.

### Cosmic Ray Effects (1962)

In Fig. 2 are the grouped cosmic ray-progeny averages for 16 generations from each of two magnets oriented east ( $N$ )-west ( $S$ ) and two separate control cultures grown at the same time and for the same number of generations. The standard variation in  $F_t$  for each point on this curve is approximately 50. There is a steady, non-linear decline in the grouped control progeny with increasing cosmic ray activity, whereas the data from the  $N$  and  $S$  magnetic field conditions demonstrate a different reproductive response effect. There appears to be a maximum in both magnetic field curves at a cosmic ray  $C_R$  value of around 0.90 (equation 2). It should also be noted in Fig. 2 that the average progeny or  $F_t$  values for the magnetic field data are higher than the control points. The  $t$  test values in Table 1 show that with the exception of the data points at the high and low end of the curves the  $N$  and  $S$  data are significantly higher than the controls.

Table 1. STATISTICAL EVALUATION OF MAGNETIC FIELD DATA SHOWN IN Fig. 2

$C_R$	$N$ -pole			$S$ -pole			Significance $P < 0.05$	Degrees of freedom
	$t_N = \frac{(\bar{N} - \bar{C})}{\sigma_d}$	Std. dev $\sigma_d$		$t_S = \frac{(\bar{S} - \bar{C})}{\sigma_d}$	Std. dev $\sigma_d$			
0.889	0.23	23.6		0.44	12.6	No		7
0.896	1.80	32.8		2.15	11.3	Yes		7
0.912	3.59	11.8		3.10	10.0	Yes		15
0.925	2.12	18.8		1.86	11.7	Yes		15
0.944	0.66	30.1		0.83	21.0	No		7

The effect producing the maxima in the progeny response curves for the magnetic field data shown in Fig. 2 appeared to be transferred to a succeeding generation. From one of the test magnets six pairs of flies were removed and an  $F_1$  generation was grown out of the field for the entire generation sequence. The results of the grouped analysis for this series are shown in Fig. 3 along with the regular control data. Since the flies from one magnet were used, only three data cells could be obtained. The maxima appear in the curves for the progeny grown out of the field conditions, whereas the regular control data appear as in Fig. 2 with the steady decline in progeny with increasing cosmic ray activity. The  $N$  and  $S$  curves also lie above the control curve and in the same relative positions as the parent curves in Fig. 2, and again only the central points on the  $N$  and  $S$  curves are significantly higher than the control values. It appears that the response effects produced by the magnetic field environments are transferred to the first generation offspring; as yet, flies have not been mated beyond the  $F_1$  generation taken out of the field.

The data shown in Fig. 2 were grouped according to total progeny. In Fig. 4 the sexes are grouped separately for the three environmental conditions. It appears that there is a subtle difference between sex ratio changes in the magnetic field and control cultures, particularly at low  $C_R$  levels.

Within the same general time span as covered by the data in Fig. 2, two other tests were also made on different mating dates and on magnets with different orientations: one magnet oriented east ( $S$ )-west ( $N$ ) and one north ( $N$ )-south ( $S$ ). The results of the grouped analysis (combining data from both magnets) are given in Table 2.

Fig. 4. Sex grouped data from two magnets (Fig. 2 series)

The maxima, although not so pronounced, are again observed when these data are plotted and the *N* pole curve lines above the *S* pole curve.

Table 2. GROUPED  $C'_R$ -PROGENY ANALYSIS FROM TWO MAGNETS WITH DIFFERENT GEOMAGNETIC ORIENTATIONS; 1962 DATA ( $F_1$  IS NUMBER OF PROGENY PER GENERATION)

$C'_R$ av.	$N$ pole	$F_t$	$S$ pole	No. of generations
0.882	211	168		6
0.906	234	189		6
0.914	246	210		6
0.934	196	178		4
0.949	191	174		5

### Solar Effects (1962)

The average solar flare  $S'_F$  values (equation 1) were much lower during the 1962 period of examination. The grouped  $S'_F$  averages for the progeny shown in Fig. 2 are listed in Table 3, and it may be seen in these data that there are no consistent trends or correlations; in fact, the progeny yields are virtually independent of solar flare activity.

Table 3. GROUPING OF 1962 SOLAR FLARE DATA SHOWING THE ABSENCE OF SMOOTH TRENDS

$\bar{S}'_F$	$F_1$ progeny per generation		
	<i>N</i>	<i>S</i>	<i>C</i>

0.151	205	153	125
0.175	207	204	185
0.232	201	184	169

### Solar and Cosmic Ray Effects (1961)

In the 1961 analysis neither the  $C'_R$  nor  $S'_F$  grouped data show smooth trends. In Table 4 are  $S'_F$  data averaged for three magnets oriented east (*N*)-west (*S*), and although in the magnetic field there is a general inverse trend or decrease in progeny with increasing solar flare activity, the data show pronounced fluctuations. In the grouped progeny data for the  $C'_R$  function (also listed in Table 4) maxima are indicated; however, the trends are not smooth. Compared with the data in Fig. 2 one cannot discuss the information obtained during the 1961 period with regard to making any comparisons or predicting trends. Taken as an isolated group, the data during 1961 disclose rather erratic variations with the extra-terrestrial environmental parameters. The lack of smooth variations during 1961 may be explained by the fact that this is

Table 4. GROUPED SOLAR FLARE AND COSMIC RAY DATA FOR THE 1961 PERIOD

$S'_F$	$F_1$ progeny per gen.			$C'_R$	$F_1$ progeny per gen.		
	<i>N</i>	<i>S</i>	<i>C</i>		<i>N</i>	<i>S</i>	<i>C</i>
0.044	113	102	125	0.769	81	70	75

0.317	67	49	58				

approximately the midpoint between solar maximum and minimum and the response of the organisms to environmental changes may be a period of transition. This transition possibility is further indicated by examining data previous to the 1961 test interval.

### Solar and Cosmic Ray Effects (1959-60)

During this period the solar activity was still high, and this appeared to be the predominant influence on the biomagnetic response effects. In Fig. 5 are the grouped  $S'_F$  data for two magnets oriented west (*N*)-east (*S*), and it may be seen that there is a regular trend in the *N* and *S* pole data with a maximum indicated at  $S'_F$  values around 2.2. The control data do not indicate this same trend, that is, the reproductive response of the flies in the magnetic field

to solar flare activity appears to be markedly different from the response in control cultures out of the field. The control data for the results given in Fig. 5 are listed in Table 5, and the absence of the smooth trend is apparent. In general, all the 1960 data (high solar flare activity) indicate that the organisms are responding to different environmental parameters depending on whether the flies are grown in or outside the magnetic field. In a later section, we will speculate about this finding in greater detail.

### Influence of Van Allen Radiation Belt

It has been shown by Forbusch, Pizzella and Venkatesan<sup>6</sup> that there is an indication of a correlation between the equatorial ring current surrounding the Earth and the radiation from the outer Van Allen belt as detected by the satellite *Explorer 7*. These authors published a series of daily measurements of both the ring current  $U$  and the counting rate  $R_b^*$  from the belt (at 4.1 Earth radii). These data extended from November 1, 1959, to August 27, 1960, or during the period when the solar activity was still high; in fact, correlations were shown between solar events and the  $U$ - $R_b^*$  variations.

During this same period of observation, progeny data were available from two magnets oriented west (*N*)-east (*S*). If the equatorial ring current  $U$  modulates the incoming radiation, then one might look for a relation between the progeny and the  $U$  parameter; that is, under the assumption that the ring current modulates at least a portion of the radiation which ultimately reaches the fields of the test magnets. This proposed relationship

Fig. 5. Reproductive response from two magnets during period of high solar activity [west (*N*)-east (*S*)]. 1959-60 data

Fig. 6. Indicated relationship between magnetic field progeny and equatorial ring current. 1959-60 data

is indicated in the grouped analysis in Fig. 6, and although a correlation is suggested many more data would have to be obtained before this influence could be stated with a high degree of certainty.

#### Barometric Pressure Influence

One of the first observations made during the initial investigations of environmental effects was the fact that there was an apparent correlation between progeny yields— $F_1$  and  $P$ —barometric pressure<sup>6</sup>. It was realized that these effects were not due to barometric pressure alone, since placing the culture bottle in an electric field reduced the  $P$  correlation and produced higher progeny yields even though the changes in pressure were the same as in control cultures. This finding was believed to be due to the influence of the electric field on the ion density within the culture bottles. Outside the electric field the primary factor would be barometric pressure; air acts as an absorber of incoming ionizing particles and high pressure would reduce the particle number. Inside the electric field the total ion density would be reduced and the variations in ion level would be less sensitive to  $P$ -changes in the environment. These experiments were all conducted during the period of high solar activity.

Beginning in 1961 and extending into the more recent analysis the high correlations between control progeny and barometric pressure were no longer obtained. This may be explained by the fact that as both the cosmic ray flux and energy increase, the influence of local barometric pressure changes becomes less significant in controlling the local ion concentration. The greatest absorption effects in the atmosphere would occur when the cosmic ray energy was low or during the observed period of high solar activity.

During the period of high correlation between progeny and barometric pressure it was found that flies grown in the magnetic field disclosed a much reduced correlation; this may be explained by the fact that the magnetic field reduced the cosmic ray component during this test period. Thus, the 1960 barometric pressure observations support the hypothesis of a combined cosmic ray-solar flare effect in cultures outside the magnetic field with the major influence on the reproductive responses of flies in the magnetic fields being solar flares. An empirical relationship was worked out<sup>1</sup> to take into account both the environmental parameters of  $P$  and  $S_F$ ; however, it now appears that this equation is only applicable during the active period in the solar cycle and should be further modified to account for the  $C_R$  parameter. If one considers all the test data examined, it may be seen that

the barometric pressure effect is in general a secondary influence and only plays a significant part during high solar and low cosmic-ray activity.

#### Tentative Mechanisms

An attempt will be made to integrate the various findings presented in the preceding paragraphs into a composite view of the changes taking place during the solar cycle. As previously pointed out, much of what will be said is based on suggested relationships and indicated trends in data which, to be well established, will have to be followed through several solar cycles. Although the trends are not always simple, the data demonstrate that the reproductive responses of *Drosophila* disclose variations which are related to changes in the terrestrial environment.

For example, in Fig. 2 the maximum points and the higher progeny of the cultures in the magnetic field may be explained in part by considering the influence of a magnetic field on cosmic ray particles. It has been shown, for example, by L. F. Curtiss<sup>7</sup> that a considerable fraction of the cosmic ray flux ( $\sim 30$  per cent) can be deflected by a magnetic field. It will be assumed that the magnets used here also deviate a portion of the cosmic ray particles out of the field region covered by the culture bottles. The amount of deflexion will depend both on the kinetic energy and on the charge of the particle, given by:

$$mv^2/\rho = Hev \quad (6)$$

where  $\rho$  is the path radius of a particle with charge  $e$ , mass  $m$ , and velocity  $v$  moving in a magnetic field of strength  $H$  gauss. For high-energy particles in the relativistic range:

$$pc/e = 300 H \rho \quad (7)$$

where  $c$  is the velocity of light and  $p$  is the so-called magnetic rigidity of the particle. When  $p$  is given in units of  $eV/c$ , the path radius of the particle in cm is given by:

$$\rho = p/300 H \quad (8)$$

These equations apply to the two-dimensional case and are, therefore, useful only when considering simplified conditions. We can, however, obtain some idea of the order of magnitude of the deflexion effect by considering charged particles arriving along the equatorial plane of the test magnets.

The cosmic ray data used in these investigations represent neutron counts produced by the local interaction of primaries; the majority of the interaction particles are probably protons and electrons. In the case of the cosmic ray data presented in Fig. 2, the deflexion of these primaries may not be great; for example, a 100-MeV particle would have a radius of curvature of approximately 3 m in a 350-gauss field which would represent the field strength at the region of the medium surface shown in Fig. 1. Such a particle approaching the magnet might be deflected slightly by the first pole and as a consequence could completely miss the test region of the adjacent bottle on the opposite pole of the magnet. A greater deviation of particles at certain energy-levels and charges could account for the maxima in the progeny response curves shown in Fig. 2, that is, through an energy selection process within the magnetic field regions.

It does appear, however, that the magnetic field 'conditions' the flies to the cosmic ray environment. The maxima in the progeny response curves were transferred to the first generation offspring; therefore, whatever conditioning occurs in the magnetic field appears to be genetically transferred. It has been shown by Reddi and Rao<sup>8</sup> that cosmic rays produce chromosomal breakage in *Drosophila melanogaster*. It is suggested that the magnetic field in some manner reduces the frequency of this chromosomal breakage by cosmic radiation. Thus, in the case of the results obtained during the recent cosmic ray period,

there exist both the deflexion effect of the magnetic fields on the cosmic ray particles as well as a possible genetically transferred conditioning effect of the magnetic field on the organism.

During the periods of high solar activity, the incoming particles are of lower energy, and it can be shown by equation 8 that the radius of curvature of a charged particle in the magnetic field is considerably smaller. For example, a 1 MeV particle approaching the equatorial plane of the magnet at the medium surface would have approximately a 3-cm radius of curvature, and as a result of its lower energy there is a greater probability that it would be 'captured' by the magnetic field and spiral into the test region of the magnet. The situation in the magnetic field is quite different during high solar activity from that during the period of high cosmic radiation. This could explain the lack of correlation of the 1960 control data (Table 5) with the  $S'_F$  parameter. Thus in the case of the control data, during the high solar flare activity the effects of both cosmic ray and solar flare radiation are acting on the organism. When encountering the magnetic field conditions, a portion of the cosmic ray component may be deflected out of the field region (as indicated for the 1962 data) and the magnetic field progeny are subjected to a lower cosmic ray flux but, by the same token, a higher solar flare flux. The arrival directions of the solar particles are such that they may first be trapped by the magnetic field of the Earth, then by the fields of the test magnets, and finally by this energy selection process exert a greater influence on the reproductive responses of flies in the magnetic field than in control cultures.

An example of the changing trends and correlations over the two periods of the solar cycle is indicated in a

Table 6. SIMPLIFIED REPRESENTATION OF PROGENY TRENDS UNDER DIFFERENT ENVIRONMENTAL CONDITIONS

Environmental condition		In magnetic field ( $N$ and $S$ )	Controls
Cosmic ray period	$\begin{matrix} \overline{C_R} \\ P \\ \overline{S_F} \end{matrix}$	$\begin{matrix} (-) \\ (0) \\ (0) \end{matrix}$	$\begin{matrix} (-) \\ (0) \\ (0) \end{matrix}$
Solar flare period	$\begin{matrix} \overline{C_R} \\ P \\ \overline{S_F} \end{matrix}$	$\begin{matrix} (0) \\ (0) \\ (-) \end{matrix}$	$\begin{matrix} (+) \\ (+) \\ (0) \end{matrix}$

very simplified form in Table 6. In this table a definite trend is indicated by a plus or minus sign depending on whether the curve has a positive or negative slope, and if the trend is uncertain or erratic it is indicated by a zero. Table 6 shows neither differences in the level of the progeny responses nor detailed variations in the curves, simply the general trends in the data.

When considering only the factors of trends in data the conditions are similar for both the magnetic field and the control data during the cosmic ray period. The trends are, however, reversed for the two environmental conditions during the period of high solar flare activity.

## IMMUNOGENICITY OF ANTIGEN-CONTAINING RIBONUCLEIC ACID PREPARATIONS FROM MACROPHAGES

By DR. BRIGITTE A. ASKONAS and DR. JOAN M. RHODES\*

National Institute for Medical Research, London, N.W.7

ATTENTION has been directed recently to the possibility that macrophages play an intermediate part in antibody formation. Over the years, evidence has accumulated that phagocytic cells in lymphoid tissues and spleens take up foreign proteins and retain them for several months (see reviews by Haurowitz<sup>1</sup> and Campbell and Garvey<sup>2</sup>). Flagellar antigen labelled with iodine-131 persists for four weeks in the dendritic macrophages of lymphoid follicles<sup>3</sup> and human serum albumin persists in such phagocytes in chick spleen<sup>4</sup>. Lysosomal fractions from spleens of animals several days after injection of red blood cells<sup>5</sup> have proved to be immunogenic, and immunogenic preparations have been obtained from spleen and liver three weeks after injection of *Shigella*<sup>6</sup> and bovine serum albumin<sup>7</sup>.

Garvey and Campbell<sup>8,9</sup> have reported that the antigen which persists in liver is complexed with nucleic acids. Fishman and Adler<sup>10</sup> found that RNA extracted with phenol from macrophages after contact with bacteriophage induced phage-neutralizing antibodies when added to lymphoid cells in tissue culture or transplantation chambers. The inducing factor was species-specific, ribonuclease sensitive, and appeared to be present in low-molecular-weight RNA fractions<sup>11</sup>.

It is an open question whether antigen can stimulate potential antibody-forming cells directly or whether passage of antigen through an intermediate cell is a necessary step in the induction of antibody globulin syn-

thesis. Macrophages may simply take up and store antigen in close proximity to immunologically reactive cells, or they may have to process antigen in some way before induction of antibody formation can occur. We have attempted to analyse this problem further. Haemocyanin was used as an antigen because it is a large molecule which can conveniently be characterized by centrifugation on sucrose density gradients. Using haemocyanin labelled with iodine-131, it has been possible to follow the fate of antigen in peritoneal macrophages and extracts made from them.

Small amounts of antigenic material were found in the aqueous phase with RNA extracted by phenol treatment of macrophages previously exposed to haemocyanin *in vivo*. The <sup>131</sup>I-label gave quantitative information about the amount of antigenic material present in the extracts, and the immunogenicity of antigen associated with RNA could be compared with that of free labelled antigen. Extracts of RNA were also made immediately after addition of <sup>131</sup>I-haemocyanin to macrophages. Such RNA preparations contained a smaller percentage of macromolecular <sup>131</sup>I-material than extracts made some time after macrophages had been in contact with haemocyanin. However, provided enough haemocyanin was added immediately before phenol extraction, the extracts were similarly immunogenic.

The results suggest that macrophages which have taken up antigen do not form a specific new informational RNA but may process antigen in some way so as to make it highly immunogenic. Whether this is a necessary step in

\* Present address: International Escherichia Centre, Statens Serum Institut, Copenhagen.

antibody formation is not clear. Some of these results have been presented at the symposium on the "Molecular and Cellular Basis of Antibody Formation" held in Prague in May 1964 (ref. 12).

**Iodination of haemocyanin.** Haemocyanin from *Maia squinado* blood was purified in columns of DEAE ion-exchange cellulose using gradient elution (0.05 M NaCl–0.05 M potassium phosphate pH 6.7 to 0.4 M NaCl in 0.05 M potassium phosphate) (Humphrey, unpublished results). It was labelled with carrier-free iodine-131 by the method of Hunter and Greenwood<sup>13</sup>. Specific radioactivities of 5–40  $\mu\text{Ci}/\mu\text{g}$  gave satisfactory preparations, but with higher radioactivities haemocyanin underwent partial degradation and loss of precipitability with specific antisera to haemocyanin.

**Test for immunogenicity.** All the experiments were carried out with inbred mice (*C<sub>3</sub>H/He*). Since soluble haemocyanin does not give a good primary response in mice, and we wished to detect small amounts of immunogenic material, we resorted to a cell transfer system<sup>6</sup> into primed mice. Normal mouse spleen cells ( $3 \times 10^7$  cells/mouse) were incubated with <sup>131</sup>I-haemocyanin or RNA preparations for 1 h at 37° C in Gey's medium and then transferred into mice that had been primed in the footpads with 5–10  $\mu\text{g}$  alum precipitated haemocyanin at least two months previously. At that time, the sera of the recipient mice had a very low antigen-binding capacity. Peak titres appeared about nine days after cell transfer. 5–6 mice were used for each group.

**Antibody assay.** The antigen-binding capacity of the mouse sera was estimated by an indirect antigen-binding test<sup>14</sup>, using <sup>131</sup>I-haemocyanin and antiserum and precipitating the antigen/antibody complex with antibody to mouse  $\gamma$ -globulin. Each tube contained 0.1 ml. saline, 0.04  $\mu\text{g}$  <sup>131</sup>I-haemocyanin (5  $\mu\text{Ci}/\mu\text{g}$ ) and 5  $\mu\text{l}$ . antiserum (or 5  $\mu\text{l}$ . of 2- and 6-fold dilutions in normal mouse serum). The reaction mixture was incubated at 37° C for 30 min and then an excess of anti-mouse  $\gamma$ -globulin was added. After incubating at 37° C once more, the volumes were made up to 1 ml. with saline. The samples were left in the cold overnight, centrifuged at 4° C and the <sup>131</sup>I-haemocyanin bound by the precipitate counted. All Ag-binding capacities were corrected for non-specific binding of <sup>131</sup>I-haemocyanin by normal mouse serum. The precipitability of each <sup>131</sup>I-haemocyanin preparation was tested with a known antiserum. Antigen-binding capacity (ABC) of the mouse sera was expressed as  $\mu\text{g}$  haemocyanin bound per ml. of antiserum at serum dilutions, at which 30 per cent of the antigen was bound. It was observed, using antiserum from mice stimulated by a secondary injection of antigen, that the plot of percentage antigen bound against log (antiserum concentration) was approximately linear between 80 and 30 per cent of antigen bound. A standard curve was used to correct antigen-binding capacity of the higher titre sera, which bound more than 30 per cent of the <sup>131</sup>I-haemocyanin at the dilutions used.

The results of the indirect antigen-binding test were also checked with a modified direct radioprecipitin test<sup>15</sup> combining binding of <sup>131</sup>I-haemocyanin by antiserum and autoradiography<sup>12</sup>.

An indirect antigen-binding test was also used to test for antigenic properties of <sup>131</sup>I-material in macrophages and RNA preparations characterized on sucrose gradients. Anti-haemocyanin from a hyperimmunized rabbit was added to the gradient fractions. After incubating for 1 h at 37° C, a slight excess of antibody to rabbit  $\gamma$ -globulin was added, and the mixture was re-incubated at 37° C for 1 h. After standing overnight at 4° C the proportion of <sup>131</sup>I-radioactivity bound by the antigen/antibody precipitate was determined. Normal rabbit serum served as a control for non-specific binding of <sup>131</sup>I-material.

**Phenol treatment of macrophages.** Three days after an intraperitoneal injection of 10 per cent proteose peptone (Difco), peritoneal cells were collected by washing out the

peritoneum with 3 ml. 1 : 20,000 heparin containing 5 per cent normal rabbit serum. Each mouse yielded about  $10^7$  cells, at least 80 per cent being macrophages, that is, cells which rapidly phagocytose particulate matter. The cells were washed twice with Gey's medium, homogenized in 0.025 M sodium phosphate buffer pH 7.0 with a 'Teflon' homogenizer, and shaken for 15 min with an equal volume of washed, re-distilled phenol either at +20° C or in an ice bath. All subsequent procedures were performed in an ice bath. The aqueous phase was re-extracted twice for 5 min with an equal volume of phenol. Phenol was removed by six extractions with washed ether. Nitrogen was then bubbled through the solution to remove ether. The ratio of the absorption density at 260 and 280 m $\mu$  was 2.

RNA was extracted from macrophages either after contact of the peritoneal cells with <sup>131</sup>I-haemocyanin *in vivo* for 2.5 h (preparation I) or after addition of <sup>131</sup>I-haemocyanin to normal macrophages immediately before homogenization (preparation II) (Table 1).

**RNA preparation I obtained from macrophages after contact with haemocyanin *in vivo*.** Preliminary experiments had demonstrated that <sup>131</sup>I-haemocyanin injected intraperitoneally into mice is taken up rapidly by peritoneal cells (peak radioactivity on macrophages occurs within 1 h). More than half the material taken up is rapidly degraded intracellularly, iodine-131 is lost from the cells, but after 2–3 h the remaining <sup>131</sup>I-radioactivity (about 0.1–0.4 per cent of the injected dose) persists in the cell for more than 24 h (ref. 12). A time-interval of 2.5 h between haemocyanin injection and collection of peritoneal cells was therefore chosen for the preparation of macrophage RNA. At that stage about two-thirds of the <sup>131</sup>I-material in the cells appears to be degraded (TCA soluble and not precipitable with anti-haemocyanin)<sup>12</sup>. One-third will be referred to as macromolecular <sup>131</sup>I-material, precipitable with trichloroacetic acid.

A typical experiment will be described in detail. Peritoneal cells were collected from 20 mice 2.5 h after intraperitoneal injection of 4  $\mu\text{g}$  <sup>131</sup>I-haemocyanin/mouse. 0.45 per cent of the injected radioactivity was then present in the washed cells. The macrophages were treated with phenol at +4° C (as described previously), yielding 750  $\mu\text{g}$  RNA containing 3 per cent of the total <sup>131</sup>I-radioactivity on the macrophages. The aqueous phase selects free iodine-131, but 10 per cent of the radioactivity was in macromolecular form (precipitated with 10 per cent TCA and with specific anti-haemocyanin serum). The presence of macromolecular iodine-131 is confirmed when the RNA is analysed on a sucrose gradient (4–20 per cent sucrose pH 7.4). Fig. 1 shows the pattern of distribution of <sup>131</sup>I-radioactivity on the gradient and the absorption density at  $D_{260}$  of the RNA. The RNA shows the usual-sized components (30 S, 16 S and small-molecular-weight material). The major proportion of the radioactive counts stays on top of the gradient (tubes 12 and 13). However, there is always some radioactivity associated with S values of the original haemocyanin preparation (tube 7) and also some <sup>131</sup>I-material with higher and lower molecular weight (tubes 3, 4, and 9, 10), which may represent partly degraded, complexed or original haemocyanin. The sedimentation behaviour of the original <sup>131</sup>I-haemocyanin

Fig. 1. Phenol-extracted macrophage RNA (Series I) after ultracentrifugation in a density gradient. O, Absorption density of RNA at 260  $m\mu$ ; ●, counts due to  $^{131}\text{I}$ , RNA preparation I; Δ, counts due to  $^{131}\text{I}$ -HCY added to normal macrophage RNA. RNA solution containing bentonite was layered on a 4-20 per cent sucrose gradient, containing 0.05 M KCl, 0.05 M *tris* buffer pH 7.4, and 0.001 M  $\text{MgCl}_2$ . Tube 13 represents the top of the gradient after centrifuging for 3.5 h at 34,000 r.p.m. in a *SW* 39 rotor in the Spinco model *L* ultracentrifuge.

mixed with normal mouse RNA can also be seen in Fig. 1. The positions of the  $^{131}\text{I}$ -peaks coincide well with sedimentation values kindly determined by Dr. P. Charlwood on an analytical ultracentrifuge. At the same pH (7.4) haemocyanin had an  $S_{20,w}$  of 26 with small amounts of aggregated and smaller molecular weight material ( $S_{20,w}$  of 36 and 15). The RNA thus contains in macromolecular form about 0.3 per cent of the  $^{131}\text{I}$ -radioactivity in the macrophages, or 0.9 per cent of the macromolecular iodine-131 present in the macrophages at 2.5 h. In the assay of immunogenicity each mouse received 1/15 of this material.

Another RNA preparation, left to stand overnight in the cold, is shown in Fig. 2. The RNA is partly degraded, probably due to traces of ribonuclease, which appears to contaminate most RNA preparations. Nevertheless, the macromolecular  $^{131}\text{I}$ -peaks are still present.

Immunogenicity of the RNA extract was tested immediately after preparation by incubation of aliquots with normal mouse spleen cells and subsequent intraperitoneal transfer into 5-6 primed mice per group (as described). Each mouse received approximately 50  $\mu\text{g}$  RNA containing macromolecular  $^{131}\text{I}$ -material of the order of 0.00004  $\mu\text{g}$  (calculated on the basis of radioactivity of the injected  $^{131}\text{I}$ -haemocyanin). The mouse sera were assayed for antibody nine days after the intraperitoneal injection. Table 2 shows results of this particular experiment; mice in the control group had titres averaging 0.73  $\mu\text{g}$  ABC/ml.; three out of five animals in the group receiving the RNA had increased serum antibody titres with a geometric mean of 17.8  $\mu\text{g}$  ABC/ml. The conditions of our assay make this difference highly significant. The second antiserum dilutions bind none or only a small percentage of the  $^{131}\text{I}$ -haemocyanin in the control mice, whereas mice in the experimental group with the higher titres bind all, or a high proportion of, the  $^{131}\text{I}$ -haemocyanin present. Pre-treatment of the RNA with 4  $\mu\text{g}$  RNase/50  $\mu\text{g}$  RNA for 30 min at 37° C inhibited the increase in serum antigen-binding capacity of the recipient mice.

Seven similar experiments were carried out, extracting RNA from cells 2.5 h after *in vivo* injection of haemocyanin or in some cases 4 h after *in vitro* incubation of

Table 2. IMMUNOGENICITY OF RNA PREPARATION I  
Indirect  $^{131}\text{I}$ -Ag binding test

Spleen cells	$\mu\text{g}$ RNA/mouse	RNase $\mu\text{g}/\text{mouse}$	$\mu\text{g}$ HCY bound/ml. mouse serum	Individual titres	Mean (geometric)
+	—	—	3.7	0.5 1.6 2.0 0.0	0.73
+	60	—	0.0	0.0 0.8 1.4 4.0	
+	60	4	3.0	3.1 81.0 61.6 38.5	17.8
+			3.6	1.6 0.0 5.6 3.6	1.64

RNA preparation I obtained from macrophages 2.5 h after injection of  $^{131}\text{I}$ -haemocyanin (HCY) *in vivo*. Spleen cells ( $3 \times 10^7$  cells/mouse) were pre-incubated with RNA preparation I 1 h at 37° C before intraperitoneal injection into mice. The recipient mice had been primed 2 months previously with 5  $\mu\text{g}$  alum-HCY in the foot-pads. In the last group 300  $\mu\text{g}$  RNA were treated with 20  $\mu\text{g}$  RNase for 30 min at 37° C before incubation with the spleen cells. The mice were bled 8 days after the transfer of spleen cells.

macrophages with  $^{131}\text{I}$ -haemocyanin when similar amounts of haemocyanin had been taken up. In most cases the cells were treated with phenol at 20° C for 20 min for the first extraction, since 20° C appeared to yield more messenger-type RNA in liver and plasma cell tumours<sup>16</sup>. Only half the RNA preparations I proved to be significantly immunogenic in the recipient mice. No visible differences in the molecular size of RNA or macromolecular  $^{131}\text{I}$ -radioactivity could be correlated with any success or failure in antibody induction.

Phenol treatment of macrophages immediately after addition of  $^{131}\text{I}$ -haemocyanin. It was important to ascertain whether active uptake by macrophages is required for the formation of an immunogenic RNA-antigen complex. As control,  $^{131}\text{I}$ -haemocyanin in amounts equivalent to those taken up by peritoneal cells *in vivo* (0.2-0.8  $\mu\text{g}$ ) was added to peritoneal cells from 20 normal mice before phenol treatment. A much lower percentage of the macromolecular  $^{131}\text{I}$ -counts was found in the aqueous RNA phase, and preparations made in this way were not detectably immunogenic. When 10-25 times the amount of  $^{131}\text{I}$ -haemocyanin taken up by macrophages *in vivo* was added to normal peritoneal cells, the absolute amount of macromolecular  $^{131}\text{I}$ -material present in the phenol-extracted RNA preparations was similar to that found in the series I RNA preparations—but only 0.03 per cent of total  $^{131}\text{I}$ -haemocyanin was recovered in macromolecular form in the phenol-extracted RNA preparation. Table 3 shows that such an RNA preparation was also immunogenic in three out of five mice. When the RNA was treated with RNase, no increase in serum antigen-binding capacity was produced.

Fig. 2. Degradation of RNA preparation I at 4° C. O, Absorption density of RNA at 260  $m\mu$ ; ●, counts due to  $^{131}\text{I}$ , RNA preparation. Sucrose gradient and conditions of centrifugation as in Fig. 1. The RNA preparation had been left to stand for 1 day at + 4° C.

Other conditions as in Table 2.

**Comparison of RNA preparations I and II.** Table 4 shows a comparison of the amounts of macromolecular  $^{125}\text{I}$ -material associated with RNA extracts. By macromolecular iodine- $^{131}\text{I}$  we mean material the sedimentation-coefficient of which is larger than  $6S$  on a sucrose gradient, which precipitates with TCA, and which retains the capacity to combine specifically with rabbit anti-haemocyanin as measured by secondary precipitation with antibody to rabbit  $\gamma$ -globulin. Normal rabbit serum served as a control. The results of typical experiments are illustrated in Table 4. The differences have been strikingly consistent in numerous experiments.

Table 4. COMPARISON OF RNA PREPARATIONS FROM MACROPHAGES AFTER *in vivo* CONTACT WITH  $^{125}\text{I}$ -HCY (I) AND IMMEDIATELY AFTER ADDITION OF  $^{125}\text{I}$ -HCY (II)

	RNA prepn. I	RNA prepn. II

Immunogenicity	+	—	+

\* Calculated on basis of the specific radioactivity of  $^{125}\text{I}$ -HCY used.

**Immunogenicity of small amounts of haemocyanin.** The immunogenicity in our assay system of small amounts of  $^{125}\text{I}$ -haemocyanin *per se* was compared with that of the RNA preparations. Table 5 shows that the minimum amount of haemocyanin giving a significant antibody response above control levels is  $0.001 \mu\text{g}/\text{mouse}$  in the spleen cell transfer system. Lower amounts did not give any significant rise in antigen-binding capacity in mice.  $0.001 \mu\text{g}$  represents an amount 20 times greater than the amount of macromolecular  $^{125}\text{I}$ -material in the RNA preparations (calculated from the  $^{125}\text{I}$ -radioactivity of the added protein). The haemocyanin was diluted in the presence of small amounts of bovine serum albumin to ensure that the haemocyanin did not stick to the glass containers, and the efficacy of this procedure was tested by measuring the radioactivity of the injected solutions. Incubation with spleen cells before transfer into primed mice is a more sensitive method for detecting antigen, since  $0.001 \mu\text{g}$  haemocyanin injected alone intraperitoneally into these mice did not increase the antigen-binding capacity of the recipients.

The use of inbred mice gave us reproducible responses. In several series of experiments it was found that  $0.001 \mu\text{g}$  haemocyanin + spleen cells was the minimum dose to

raise the serum antigen-binding capacity of recipient mice. With this low dose generally three or four out of five recipients responded (Tables 5 and 6). Doubling the dose to  $0.002 \mu\text{g}$  haemocyanin induced higher titres in all recipients.

Pre-incubation of haemocyanin and spleen cells with ribonuclease up to levels of  $8 \mu\text{g}$  RNase per mouse did not affect the response appreciably (Table 6).

\* Antigen-binding capacity of recipient mice 8 days after transfer of spleen cells. Spleen cells ( $3 \times 10^7/\text{mouse}$ ) were pre-incubated with  $^{125}\text{I}$ -HCY 1 h at  $37^\circ$  before injection into primed mice. In the groups with RNase, the  $^{125}\text{I}$ -HCY was treated with the stated amount of RNase for 30 min at  $37^\circ$  C before incubation with the spleen cells.

## Discussion

It has been suggested<sup>10</sup> that phenol-extracted RNA from rat peritoneal cells by inducing phage neutralizing activity, contains information for the synthesis of specific antibody. Similarly, RNA from rabbit lymph glands has been reported to transfer transplantation immunity<sup>17</sup>. We found that RNA preparations obtained by phenol treatment of mouse peritoneal cells 2.5 h after contact with  $^{125}\text{I}$ -haemocyanin *in vivo* can be immunogenic in primed mice, but we obtained evidence of the presence of antigenic  $^{125}\text{I}$ -material in the RNA preparations. Furthermore, RNA preparations made immediately after the addition of  $^{125}\text{I}$ -haemocyanin to peritoneal cells also proved to be immunogenic, although it was necessary to add about 20–30 times as much  $^{125}\text{I}$ -haemocyanin to obtain similar amounts of macromolecular  $^{125}\text{I}$ -material in the aqueous RNA phase (Table 4). Thus, at least in our system the immunogenicity of the RNA preparations is not due to the formation of a specific new informational RNA by macrophages following contact with antigen.

The finding that small amounts of protein contaminate phenol-extracted RNA agrees with the experience of other workers, who found, for example, trace amounts of enzymes and virus proteins associated with phenol-extracted RNA. None the less, it was striking that a far greater percentage of macromolecular  $^{125}\text{I}$ -material was found in the macrophage RNA preparations after cellular uptake of haemocyanin *in vivo* than after addition of  $^{125}\text{I}$ -haemocyanin to peritoneal cells just before phenol treatment (Table 4). This difference has been consistently observed in many experiments. The other point which emerges is that both types of RNA-Ag preparation can be highly immunogenic compared with haemocyanin alone. The minimum amount of haemocyanin eliciting similar increases in serum antigen-binding capacity in recipient mice is  $0.001 \mu\text{g}$  haemocyanin, about 20 times the amount calculated to be present in the immunogenic RNA preparations.

In the control RNA extracts (II) it seems probable that antigen is bound by RNA, and RNA simply enhances uptake of antigenic material by the relevant cells. This would explain the inhibition of antibody response after pre-treatment of the RNA preparation with ribonuclease. The results after *in vivo* uptake of haemocyanin suggest that, in addition, an active process may take place in the macrophages.

It is thus still not possible to decide whether macrophages are essential for the induction of antibody formation. By taking up foreign material in lymphoid tissues they may bring the antigen close to potential antibody forming cells in the tissues. Several possible functions may be cited. Macrophages may simply serve as a storage

Table 5. IMMUNOGENICITY OF SMALL AMOUNTS OF HCY  
Indirect  $^{125}\text{I}$ -Ag binding test

Spleen cells	$^{125}\text{I}$ -HCY $\mu\text{g}/\text{mouse}$	$\mu\text{g}$ HCY bound/ml. mouse serum					Mean (geometric)
		Individual titres					
+	0.001	60.0	28.8	4.8	45.0	51.0	28.0
+	0.0005	1.6	3.6	3.0	4.0	1.4	2.5
+	0.0001	0.3	1.6	0.9	1.8	1.8	1.07
+	0.00005	1.5	1.3	0.3	0.3	0.4	0.59
+	—	0.5	4.0	1.0	0.75	2.5	1.30
—	0.001	0.3	1.6	3.0	2.5		1.32

Spleen cells ( $3 \times 10^7$  cells/mouse) were pre-incubated with  $^{125}\text{I}$ -HCY for 1 h at  $37^\circ$  C before intraperitoneal injection into primed mice. The recipient mice had been primed 2 months previously with  $10 \mu\text{g}$  alum-HCY and were bled 9 days after cell transfer.

depot, have nothing to do with antibody formation or, alternatively, be responsible for an essential step in inducing synthesis of antibody globulin. It is probable that antigens on whole cells, particulate antigens, or bacteria have to be processed or partly degraded in macrophages to release and make available appropriate antigenic determinants to the reactive lymphoid cells. Our evidence suggests that processing of a soluble protein (haemocyanin) is not necessary to obtain immunogenic material (RNA preparation II), but the yield of immunogenic material from macrophages that had actively taken up haemocyanin is much higher (RNA preparation I). Further characterization of the immunogenic material is necessary to decide whether an active complexing or binding of antigen or its fragments with RNA (or other substances present in aqueous phenol extracts) takes place, perhaps as a mechanism of protecting antigen against lysosomal digestive enzymes. It is striking that although the major proportion of haemocyanin taken up by peritoneal cells is rapidly degraded, a small amount of antigen persists for many days in macrophages (Askonas and Rhodes, to be published), suggesting some binding or protective mechanism. Dutton and Harris<sup>20</sup> also presented evidence that spleen cells, irradiated and killed after incubation with serum albumin, liberate a factor stimulating a secondary antibody response *in vitro* (as measured by DNA synthesis). Ten times the amount of HSA as such was without effect. Possible transfer of material between macrophages and lymphocytes has been discussed by a number of workers<sup>11,17-19</sup>.

Our conclusions are that RNA preparations extracted with phenol from mouse peritoneal cells after uptake of <sup>125</sup>I-haemocyanin *in vivo* are immunogenic in primed mice. The RNA contained macromolecular <sup>125</sup>I-radioactivity with properties compatible with the presence of antigen or fragments thereof. RNA extracts prepared from macro-

phages immediately after addition of <sup>125</sup>I-haemocyanin were also immunogenic, provided larger amounts of <sup>125</sup>I-haemocyanin had been added to the macrophages. Pre-treatment of the RNA preparations with RNase in each instance diminished the antibody response.

The minimum amount of <sup>125</sup>I-haemocyanin eliciting increases in the serum antigen-binding capacity in primed recipient mice was 0.001 µg/mouse. This is 20 times the amount calculated as being present in the immunogenic RNA preparations. This response was not susceptible to low levels of ribonuclease, which inhibited the immunogenicity of RNA preparations.

We thank Mr. Brian Wright and Mrs. Frances Gotch for their assistance.

## Staphylococcus PHAGE-BACTERIUM IN VIVO INTERACTION

By DR. PASQUALE F. BARTELL, ARLENE GEFFEN, THOMAS ORR  
and PROF. WILLIAM S. BLAKEMORE

Harrison Department of Surgical Research, University of Pennsylvania, Philadelphia

*STAPHYLOCOCCUS aureus* has remained a constant threat to man by virtue of its ubiquity, physiological versatility, and ability to cause disease. Recent experience with antibiotic-resistant strains has led to the frank recognition of our uncertain position and has stimulated the search for a better understanding of this microbe, its pathogenic nature and its reliable control.

The clinical use of *Staphylococcus* bacteriophage lysate has been disappointing<sup>1</sup>, and its use appears to have been reserved for those situations in which all else has failed and little hope remains. Despite this circumstance, favourable results have been achieved<sup>2</sup>. Unfortunately, it has not been possible to recognize a satisfactory *modus operandi* which might account for success or failure in the use of these preparations. Therefore, it is our purpose to investigate the use of bacteriophage lysate in staphylococcal infection, to determine its potential and to establish its limitations as a lytic and/or immunoprophylactic agent.

In a previous report<sup>3</sup> we presented evidence to indicate that *S. aureus*, Type 80/81 and bacteriophage 81 were capable of *in vivo* interaction, resulting in 81 per cent survival of infected mice. This article describes certain factors which appear to influence the degree of interaction and extent of subsequent protection of infected mice.

The experimental system under investigation consisted of male Swiss mice (14-16 g) which were infected intra-

peritoneally with  $1.5 \times 10^8$  *S. aureus*, Type 80/81 suspended in 5 per cent gastric mucin (Wilson granular mucin, type 1701-W). Phage 81 was administered into the opposite side of the peritoneum, and plasma-levels of phage were established by bleeding groups of 5 mice from the tail at certain intervals of time. Blood was collected in cold heparinized saline (50 µ/ml.) and was centrifuged at 1,230 relative centrifuged force for 10 min, and the supernates were titrated according to procedures outlined by Adams<sup>4</sup>.

Features of the *Staphylococcus* phage-bacterium *in vivo* interaction are presented in Fig. 1, which shows the plasma-levels of phage 81 at various intervals of time after administration to infected and uninfected mice. In the uninfected group (broken line), approximately  $10^{5.5}$  p.f.u./ml. (plaque forming units/ml.) plasma were present in the 30-min sample, and this level persisted without significant change throughout the 2-h observation period. In contrast, infected mice (solid line) did not show evidence of circulating phage at 30 min. However, by 90 min the levels of phage had risen to  $10^{6.5}$  p.f.u./ml., exceeding the levels seen in uninfected mice by some 90 per cent. These results permit the interpretation that the administration of *Staphylococcus* bacteriophage to infected mice results in: (1) adsorption of phage to the infecting bacterial cell, followed by (2) a rise period and significantly increased levels of circulating phage. Distinction of this series of

Fig. 1. *Staphylococcus* phage-bacterium in vivo interaction

Fig. 2. Influence of input multiplicity on phage-bacterium interaction

events has made it possible to follow the interaction under various conditions and, further, to correlate the features of this event with subsequent protective activities observed in mice.

The effect of treating staphylococcal-infected mice with various concentrations of phage has been determined. In this experiment various groups of mice were infected and treated with decreasing numbers of phage particles so that the input multiplicity was varied from 1 to 0.001. The results are illustrated in Fig. 2. A comparison of phage plasma-levels in infected (solid line) and corresponding uninfected groups (broken line) indicates that interaction occurred at all the multiplicities tested. This was made evident by a period of adsorption followed by a rise period and significantly increased levels of phage. It will also be observed that, as input multiplicity was decreased, the rate of phage appearance in the blood decreased, and within the time limit imposed, lower levels of circulating phage were evident at the end of 2 h. This probably indicates that as input multiplicity was decreased, the proportion of bacteria initially infected by phage was also decreased, resulting in a more gradual development of the rise period.

When intraperitoneal infection of mice was initiated as already described here, the immediate administration

Fig. 3. Influence of time of phage administration on phage-bacterium interaction

of lysate containing an equal number of phage particles resulted in 80 per cent protection. The degree of protection was found to be strongly dependent on the time of phage administration; the greater the time-interval between infection and phage administration, the less the protective activity. Therefore, it was of interest to determine if reduced protective activity was directly related to a diminished interaction between phage and infecting bacteria, possibly during the period of adsorption. Groups of mice were infected and phage was administered at 0, 5, 15 and 30 min post-infection. The results are presented in Fig. 3. When phage was administered immediately after the infecting organism, the resultant curve indicated a period of adsorption followed by increased phage-levels. Phage administered 5 min after infection did not appear to be as completely adsorbed as indicated by the higher phage-levels present in the 30-min plasma sample. With further delay of 15 and 30 min before phage administration, there was little evidence of adsorption. However, in contrast to the uninfected control groups, these groups did eventually show increased phage-levels that may be suggestive of phage-bacteria interaction at some site other than the peritoneum.

Table 1. CORRELATION OF PHAGE-BACTERIUM INTERACTION AND MOUSE SURVIVAL

Phage admin. after Staph. infection min.	Relative phage adsorption (%)	Mouse survival (%)
0	99.9	80
5	90	65
15	6	10
30	0	0

The correlation which was found to exist between phage-bacterium interaction and mouse survival is shown in Table 1. It is evident that when phage was administered without delay adsorption was greatest, and that the degree of adsorption was rapidly diminished with delayed administration of phage. It is also apparent that the greater the degree of adsorption the higher the percentage survival of mice, and conversely, when adsorption was low or absent, the survival of mice was also correspondingly low or absent.

## AMINO-ACID CONTROL OF STREPTOMYCIN ACTION ON MAMMALIAN CELLS

By PROF. MERWIN MOSKOWITZ and NORMAN KELKER

Department of Biological Sciences, Purdue University, Lafayette, Indiana

**S**TREPTOMYCIN in relatively high concentration is toxic for some strains of mammalian cells<sup>1</sup>. Cells resistant to streptomycin were detected in cultures of sensitive cells and maintained their resistance on repeated sub-culture. Although sensitivity and resistance could be demonstrated under a given set of conditions, variations in the culture media affected the response of the cells to streptomycin. For example, a sensitive strain of cells manifested various degrees of resistance when different lots of horse serum were used in the media<sup>1</sup>.

We recently noted that all our strains of cells began to respond to streptomycin in an identical manner; they remained healthy and there was but a slight inhibition of growth (Fig. 1). All attempts to elicit the former pattern of sensitivity and resistance utilizing horse sera from different sources failed. Inasmuch as the sensitivity of the cells in our early observations was apparently due to a property of the serum used at that time, an examination of nutritional factors affecting sensitivity was initiated.

The conditions for determining the effect of streptomycin on cells were those described previously<sup>1</sup>. Synthetic medium 1066 (ref. 2) was utilized unless otherwise stated, streptomycin was added in a concentration of 3 mg/ml., and a clone culture of strain *L* mouse fibroblasts was used in the tests.

The cells were killed by streptomycin when medium 1066 was supplemented with 10 per cent 'Agamma' horse serum (a commercial preparation from which all the  $\gamma$ -globulin and half the  $\beta$ -globulin were removed) (Fig. 1). The cells were also sensitive when the  $\beta$ - and  $\gamma$ -fractions of horse serum (Fractions II and III) were added to the 'Agamma' horse serum supplement. These fractions apparently were not involved in the lack of sensitivity of the cells in whole horse serum, and the sensitive reaction in 'Agamma' horse serum was probably due to the removal of other components or an alteration in the serum components during processing.

The strain of cells utilized was able to grow in medium 1066 or in Eagle's amino-acid and vitamin mixture<sup>3</sup> containing 10 per cent beef peptone dialysate. Although the cells were killed by streptomycin in the 1066-peptone medium, they remained healthy in Eagle's-peptone medium plus streptomycin (Fig. 1).

Medium 1066 is much more complex than Eagle's mixture, and there is a variety of compounds present in medium 1066, and not present in Eagle's mixture, that may have caused the differences in the reactions of the cells to streptomycin. One outstanding difference in the two media is the presence of 260 mg/l. of cysteine in medium 1066 and none in Eagle's mixture. When this amount of cysteine was added to Eagle's-peptone medium the cells were killed by streptomycin in it; as little as 100 mg/l. had the same effect.

The concentration of cysteine utilized had no effect on the growth of the cells in the absence of streptomycin. Cysteine would probably be oxidized to a great extent under the test conditions, and tests with cystine gave identical results. The addition of larger amounts of other individual amino-acids in Eagle's mixture caused some enhancement of the action of streptomycin, but this occurred at levels of 400 mg/ml., at which concentration the amino-acids themselves were slightly toxic to the cells.

The cells were not killed by streptomycin in Eagle's mixture plus 'Agamma' horse serum, and there was less inhibition of growth with Eagle's mixture than with medium 1066 with horse serum. The addition of 200 mg/l. of cysteine to the Eagle's mixture caused the cells to respond in a manner identical to that observed with medium 1066 with the respective serum supplements (Fig. 1).

Cells sensitive to the action of streptomycin have been observed to be unaffected by dihydrostreptomycin<sup>4</sup>. The addition of cysteine to Eagle-peptone medium or an excess of cysteine to 1066-peptone medium did not affect the cells' reaction to dihydrostreptomycin.

These results indicate that the quantity of a single amino-acid in the growth medium is a determining factor in the response of mammalian cells to streptomycin. The fact that a sufficient amount of cyst(e)ine is requisite for streptomycin to act when 'Agamma' horse serum is used as a medium supplement suggests that the prime role of the serum supplement is to provide for the growth of the cells and that it has no special role in the action of streptomycin on the cells. It has been observed that serum binds half-cystine residues from medium<sup>5</sup>, and differences in the response of cells to streptomycin with different samples of horse serum may perhaps be explained on the basis of variations in the ability of the respective serum samples to bind cyst(e)ine or other amino-acids.

Fig. 1. Cell counts after seven days growth. Inoculum — 100,000 cells. Dead cells were killed within 48 h. Lined bars, no streptomycin; dotted bars, streptomycin added, cells healthy; black bars, streptomycin added, cells dead. E, Eagle's mixture; 66, medium 1066; HS, horse serum; AH, 'Agamma' horse serum; P, peptone; C, cysteine

Variations in the amino-acid content of a growth medium can affect the permeability, RNA synthesis, and other regulatory mechanisms of cells<sup>6</sup>. Alterations such as these in the behaviour of the cells by the added cyst(e)ine may be involved in their sensitivity to streptomycin; however, recent findings on the mode of action of streptomycin on bacteria suggest yet another hypothesis as to its possible role.

Streptomycin causes misreading of the genetic code in an *in vitro* system and may be toxic for cells by causing the production of large amounts of abnormal or non-functioning proteins<sup>7</sup>. There appear to be streptomycin-activated suppression mechanisms in bacteria, and with some strains of *E. coli* streptomycin may cause 'over-suppression', leading to the production of lethal amounts of faulty protein<sup>8</sup>. Perhaps streptomycin alters the coding properties of mammalian cells in a manner such that an abnormal protein containing a relatively large amount of a particular amino-acid is specified. If this amino-acid is present in sufficient quantity to permit the

production of lethal amounts of this protein, the cell is killed. The hypothesis assumes that the abnormal protein formed by the cell strain utilized in this work has a high cystine content; if other strains of cells are stimulated to produce abnormal proteins with a high content of a different amino-acid, that amino-acid may be required in relatively large quantities in the medium for streptomycin to be toxic for them. This possibility is being investigated.

## RELATIONSHIP OF BARR BODIES, NUCLEAR SIZE AND DEOXYRIBONUCLEIC ACID VALUE IN CULTURED HUMAN CELLS

By DR. URSULA MITTWOCH, MRS. KUSUM P. LELE and W. S. WEBSTER

Galton Laboratory, University College, London

THE results of recent work have greatly clarified our knowledge as to the origin of the Barr body. There can no longer be any doubt that a Barr body represents a single X-chromosome in a heavily condensed state. It is much less clear why tissues of female origin should contain a proportion of cells in which Barr bodies cannot be seen<sup>1</sup>. Evidence has previously been presented that, in human cell cultures, nuclei containing a Barr body are on an average somewhat smaller than those without one<sup>2,3</sup>. It has now been possible to obtain more exact measurements relating to this problem, by removing the variation in nuclear size due to polyploidy. The results indicate that nuclear size may be a major factor in determining whether a Barr body is to be formed or not.

The cells originated from skin biopsies, which were cultured according to the method of Harnden<sup>4</sup>. Two different cultures were used, both of which had apparently normal XX sex chromosomes. Culture A, which had been growing for 9 weeks and had been sub-cultured 9 times, had an apparent trisomy (with translocation) of chromosomes in the 13-15 group (Dr. J. H. Edwards, private communication); culture B, which had been growing for 6 weeks and had been sub-cultured 5 times, had an apparently normal karyotype.

After trypsinization, the cells were allowed to grow on cover slips for 25 h, when they were immediately fixed in 95 per cent ethanol for 0.5 h. They were stained by the Feulgen reaction, following hydrolysis in N hydrochloric acid at 60°C for 10 min. DNA measurements were carried out using a Barr and Stroud integrating microdensitometer GN2, which is based on the instrument designed by Deeley<sup>5</sup>. The assumption underlying this technique is that the amount of light absorbed by Feulgen-stained nuclei bears a direct relationship to the amount of DNA present. The actual technique has recently been described by Burks and Bakken<sup>6</sup>. The

cells were mounted on glass slides and no attempt was made to squash them, it having previously been shown that such preparations are suitable for assessing the ploidy of interphase nuclei<sup>7</sup>.

For each nucleus, the following particulars were recorded: (1) the presence or absence of Barr bodies (in culture B, which contained a considerable proportion of cells with multiple chromocentres, this fact was also recorded); (2) the length of the two main axes, as measured with a micrometer eye-piece; (3) the amount of light absorbed, as recorded by the integrating microdensito-

Fig. 1. Frequency distribution of DNA values in cultured cells. a, culture A; b, culture B

meter. From both cultures, 250 nuclei were recorded, but for the purpose of the present investigation nuclei which were in mitosis were excluded.

Nuclear areas were computed according to the formula  $\pi ab$ , where  $a$  and  $b$  are half axes, and the products converted into square micra, using a stage micrometer. For the purpose of plotting DNA values, the voltage readings of individual nuclei were converted into logarithms and multiplied by the reciprocal of log 2, resulting in a log scale in which any value is separated from double its value by one unit.

The DNA values are shown in Fig. 1. The two peaks in both cultures are separated by exactly one unit, and, although the values obtained are arbitrary, it is reasonable to assume that the distributions on the left and the right represent the diploid and tetraploid values respectively. The cells in the intermediate range are presumed to be in the process of synthesis. The tetraploid cells probably represent a heterogeneous group, consisting of at least three populations: (1) cells which have completed DNA synthesis prior to mitosis; (2) cells which, having completed DNA synthesis, nevertheless do not enter mitosis<sup>8,9</sup>; (3) cells which will eventually enter into tetraploid mitosis.

The mean nuclear areas, classified according to their DNA values and the presence or absence of sex chromatin, are given in Tables 1 and 2. For each culture, the difference between any two means in the diploid range is significant at the 1 per cent or a lower level. The size distributions of the diploid nuclei in culture *B* are shown in Fig. 2. It is apparent that nuclei which lack a Barr body tend to be larger than those which contain one. Previously the average difference was estimated at about 6 per cent<sup>2,3</sup>, but it now appears that for any given DNA range the difference is larger. The results presented here further indicate that nuclei with multiple chromocentres are considerably smaller than those either with or without Barr bodies.

The difference in size between nuclei without a Barr body, with one Barr body and with chromocentres appears to hold also in cells with higher than diploid DNA values (Tables 1 and 2), but the available results are too small to be significant. The average size of tetraploid nuclei with two Barr bodies was strikingly large. The relationship of Barr bodies to nuclear size in cells with polyploid DNA values requires further investigation.

The larger size of nuclei without Barr bodies in diploid cells is in agreement with the suggestion by Austin and Amoroso<sup>10</sup> that the lack of Barr bodies in early embryos<sup>11</sup>

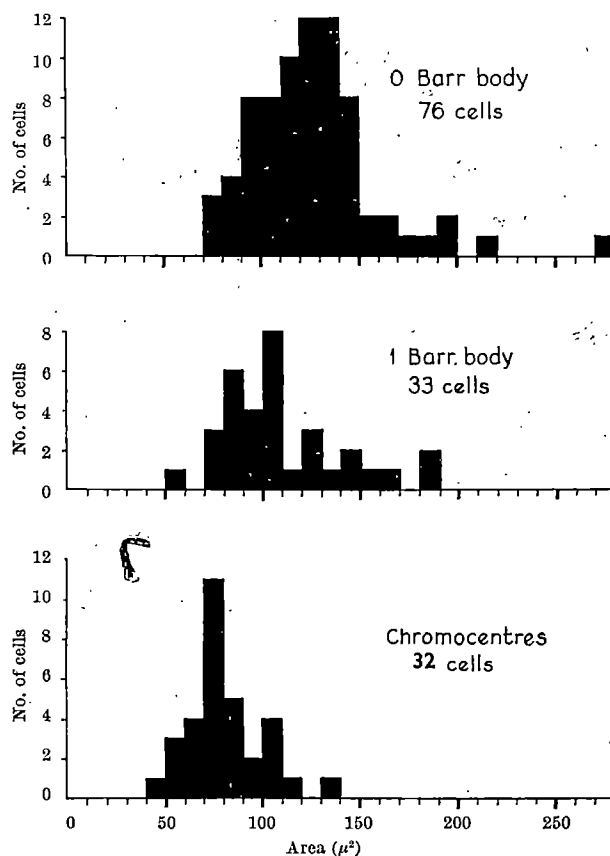

Fig. 2. Frequency distribution of nuclear areas of diploid cells from culture *B*.

is connected with the large size of their nuclei and that sex chromatin is not formed until the nuclei become sufficiently small.

It now appears that in the largest diploid nuclei neither X-chromosome has a tendency to condense, while in the smallest nuclei parts of chromosomes other than the X are likely to condense and thus obscure the presence of a Barr body; but in nuclei of intermediate size, one of the X-chromosomes tends to condense preferentially and forms a Barr body.

Commoner<sup>12</sup> has left open the question whether the difference between euchromatin and heterochromatin is due either to nucleotide composition, or to the macromolecular configuration (for example, coiling) of the polynucleotide. Although certainly not conclusive, the evidence available from the sex chromatin of mammals appears to favour the hypothesis of coiling, which is essentially a reversible process and therefore more likely to account for the presence or absence of sex chromatin in different nuclei. According to this assumption, a Barr body would represent an X-chromosome which is more tightly coiled than other major parts of a chromosome in a particular nucleus, an occurrence which is itself dependent on the macromolecular configuration of the rest of the nuclear material. The explanation that the heterochromatin of sex chromosomes may be due to differential spiralization is in accordance with the view of White<sup>13</sup>.

Any evaluation of the effect of nuclei other than those containing a visible Barr body with regard to the hypothesis of inactivation of the X-chromosome, as proposed by Lyon<sup>14-16</sup>, will have to await more detailed knowledge of the specific activity of the X-chromosomes, and the genes borne on them, in these cells.

We thank Dr. J. H. Edwards and Dr. J. Jancar for supplying the skin biopsies and Prof. L. S. Penrose for advice. The integrating microdensitometer was provided by the Central Research Fund, University of London.

Table 1. NUCLEAR AREAS, CLASSIFIED ACCORDING TO DNA VALUES AND SEX CHROMATIN STATUS  
Culture *A*

DNA value	Sex chromatin status	No. of cells	Mean nuclear area ( $\mu^2$ )	S.D.
Diploid	$\{B_0$	49	141.28	42.42
	$\{B_1$	86	119.62	37.22
Intermediate (triploid)	$\{B_0$	4	177.00	35.52
	$\{B_1$	10	128.00	32.98
Tetraploid	$\{B_0$	8	179.75	52.52
	$\{B_1$	50	157.12	52.17
	$\{B_2$	9	248.00	52.71

$B_0, B_1, B_2 = 0, 1, 2$  Barr bodies, respectively.

Table 2. NUCLEAR AREAS, CLASSIFIED ACCORDING TO DNA VALUES AND SEX CHROMATIN STATUS

## CYTOTOXIC ACTIVITY COMPARED WITH PHOTOMETRIC MEASUREMENTS OF SELECTED ALKYLATING AGENTS

By R. P. SANDERSON\*, DR. J. M. MCKENNA and PROF. W. S. BLAKEMORE

Harrison Department of Surgical Research, Schools of Medicine, University of Pennsylvania, Philadelphia

It has long been desired to be able to measure chemically the fate of anti-tumour compounds following injection. It has also been desired to attempt to correlate anti-tumour activity, as measured by biological or cytotoxic activity, with what we may call chemical concentration of a particular compound or its presumed active group. Without resorting to rather expensive isotopic techniques, this has not been practical. Epstein *et al.*<sup>4</sup> and Klatt *et al.*<sup>6</sup> reported that the reaction of  $\gamma$ -(4-nitrobenzylpyridine) with various ethylenimines or alkylating agents produces a blue colour after further treatment with base. The method depends on the replacement of one Cl<sup>-</sup> by *p*-nitrobenzylpyridine and the subsequent development of blue colour in triethylamine. Linford<sup>7</sup> has measured the hydrolysis rates of three alkylating agents and their reactions with constituents of human blood serum. He found that 'Chlorambucil', chemically very similar to phenylalanine mustard (PAM), was absorbed to serum proteins *in vitro* more rapidly than 'Cytosan', and concluded that such serum protein condensation may be a source of waste of administered drug.

In our laboratory a series of experiments was designed in order to determine the chemical and biological fates of selected alkylating agents after injection into rabbits, and preliminary results have been published<sup>10</sup>.

The four compounds examined were nitrogen mustard (HN<sub>2</sub>) NSC 762, alanine mustard (AlHN<sub>2</sub>) NSC 17663, phenylalanine mustard (PAM) NSC 8806 and 'Cytosan' NSC 26271. (These compounds were received from the Cancer Chemotherapy National Service Center of the National Cancer Institute.)

The colorimetric procedure utilizing nitrobenzylpyridine and triethylamine has been described by Klatt *et al.*<sup>6</sup> and will be referred to hereafter as the NBP-TEA test. Alcohol precipitation was accomplished according to the methods of Linford<sup>7</sup> and was used whenever photometric measurements were to be done. The cytotoxic metabolic inhibition (CMI) test was used to determine biological activity and is described elsewhere<sup>8</sup>.

For *in vivo* investigations, male albino rabbits weighing about 3 kg were given a single intravenous injection of one of the compounds being examined. The rabbits were assumed to have an extracellular fluid volume of about 500 ml., and the compounds were injected in concentrations such that 1 ml. of serum might be expected to have maximal cytotoxicity exerted by the minimal amount of compound. All animals were bled by cardiac puncture 5 min, 30 min and 60 min after injection. The blood was chilled immediately and the separated serum frozen in dry ice and alcohol and stored at -20° C until tested. The clotted blood was homogenized in a Waring blender, treated with absolute ethyl

alcohol and centrifuged, and the chemical concentration of each compound was determined in the supernatant fluid.

Preliminary investigations using the NBP-TEA test showed linearity between optical density at 565 m $\mu$  and drug concentration over a range of 2-100  $\mu$ g/ml. for HN<sub>2</sub>, AlHN<sub>2</sub> and PAM when the compounds were dissolved in either 0.85 per cent saline or normal rabbit serum. Freshly prepared 'Cytosan' was not consistently measurable by the NBP-TEA test.

In order to effect a comparison of *in vitro* and *in vivo* biological and chemical activity and to determine the stability of these four compounds as they might be used clinically, each was dissolved in 0.85 per cent saline at 1 mg/ml. and allowed to stand at room temperature over a period of 6 days. Samples were taken at intervals, shell frozen in dry ice and alcohol and stored at -20° C until all the samples had been accumulated. Colorimetric assays and cytotoxicity tests were carried out on each sample.

The results of duplicate titrations are given in Fig. 1. There was a decrease both in apparent molarity by the NBP-TEA test and in cytotoxicity by the CMI test for AlHN<sub>2</sub>, HN<sub>2</sub> and PAM, which decrease was in proportion to the respective apparent molar concentrations of each of the compounds. With time, 'Cytosan' increased by both parameters.

Fig. 2 presents the mean values in serum samples for eight animals each given a single intravenous injection of each of the compounds so that the serum at time 0 would contain the apparent molar concentrations shown on the left ordinate. Neither AlHN<sub>2</sub> nor HN<sub>2</sub> had any significant activity by either assay 5 min after injection. There was no increase in the apparent molarity of 'Cytosan' (as determined by optical density) in contrast to the three-fold increase in apparent molarity seen *in vitro* (Fig. 2). In the face of this stability of apparent molarity measured by optical density, the cytotoxicity increased 3- to 4-fold. PAM showed a decrease in apparent molarity similar to AlHN<sub>2</sub> and HN<sub>2</sub> but without a concomitant decrease in cytotoxicity. Indeed, an increase in cytotoxicity was apparent. Serial dilutions of the 30-min serum samples from four of the animals administered PAM were made simultaneously with serial dilutions of PAM freshly prepared in normal rabbit serum. These animals had received 50 mg of PAM, and, with an extracellular fluid volume of 500 ml., the serum samples were expected to contain 0.1 mg/ml.

The results of the cytotoxicity tests of these preparations are shown in Fig. 3. It is readily apparent that a PAM concentration of 10<sup>-5</sup> mg/ml. in serum 30 min after injection retained full toxic activity, while the freshly prepared samples began to lose toxicity in concentrations of < 10<sup>-2</sup> mg/ml. Thus, it seemed that the toxicity of PAM was not related to the presence of intact chloroethyl groups alone.

$$\text{Apparent molarity} = \frac{\text{O.D. at time } t}{\text{O.D./mole at time 0}}$$

Fig. 2. Comparison of chemical concentration as measured by the NBP-TEA test with cytotoxic activity with respect to time *in vivo*. The time 0 points on B reflect the cytotoxic activity of the apparent molar concentrations of each of the compounds at time 0 in A.

$$\text{Apparent molarity} = \frac{\text{O.D. at time } t}{\text{O.D./mole at time 0}}$$

Since Linford<sup>7</sup> found that 'Chlorambucil' had a characteristic absorption spectrum with a maximum at 258  $\text{m}\mu$ , it was felt that perhaps PAM might exhibit some change in its absorption spectrum which could account for the increased cytotoxicity *in vivo*. PAM was dissolved in normal rabbit serum. The serum was deproteinized with ethyl alcohol according to Linford<sup>7</sup> and the absorption spectrum determined against the normal rabbit serum-ethyl alcohol blank. PAM was found to have an absorption maximum at 258  $\text{m}\mu$  using a Beckman model DU spectrophotometer. Five and 30 min after the intra-

'Cytozan'	5	0.01	0.01

venous injection of 50 mg of PAM into each of three rabbits, blood was withdrawn by cardiac puncture and allowed to clot in ice. After separation, the clots were homogenized in water in a Waring blender at 4° C, and both sera and the supernatant fluid from the blood clots were deproteinized with ethyl alcohol. Optical densities were determined at 258  $\text{m}\mu$  and parallel NBP-TEA tests were carried out on portions of the same samples.

The results, given in Table 1, show that 100 per cent of the PAM was recovered from the blood at both 5 and 30 min after injection when assayed at 258  $\text{m}\mu$ . However, only 56 per cent of the PAM was recoverable in 5 min and none was recoverable in 30 min when the NBP-TEA test was used. Of additional interest was the observation that approximately three times as much PAM was found in the blood clot as in the serum, regardless of the test used to measure it. No shift was seen in the absorption spectrum of PAM in the serum samples which might account for the consistently observed increase in cytotoxicity.

It might be suggested that these compounds alkylate serum proteins and that the loss in apparent molarity (Fig. 2A) after injection was due to this alkylation. To test this possibility, each of the compounds was dissolved at 1 mg/ml. in pooled normal rabbit serum and allowed to stand at 37° C for 30 min. The results of the NBP-TEA tests made on these samples, given in Table 2, show that only Al  $\text{HN}_2$  exhibited a decrease in optical density during this period. These results are in general agreement with those of McAllister *et al.*<sup>8</sup>, who found that  $\text{HN}_2$  retained about 25 per cent of its cytotoxic activity when measured by the CMI test after storage for 4 h at 37° C in human serum. Thus, it would appear that the loss in apparent molarity of  $\text{HN}_2$  and PAM *in vivo* is due not to protein binding but rather to removal from the blood in the

case of  $\text{HN}_2$  or to some as yet unknown mechanism.

'Cytozan' is considered to require modification of the molecule by processes which occur *in vivo* before the terminal chlorine atoms become active<sup>1,5</sup>. Foley *et al.*<sup>5</sup> have postulated an enzymatic hydrolysis of 'Cytozan' to cytoxyl alcohol or cytoxyl amine primarily by enzymes of the mammalian liver. 'Cytozan' has also been reported

Fig. 3. Comparison of cytotoxicity of PAM freshly prepared in normal rabbit serum with 30-min serum samples of rabbits injected with PAM

to be inactive in mammalian cell cultures<sup>2</sup> when the culture method of Eagle and Foley was used<sup>3</sup>. However, when the CMI test was used, a consistent low level of cytotoxicity was observed<sup>9</sup>. Quite possibly, two mechanisms may obtain for the activation of 'Cytozan'. Conceivably, prolonged incubation (as used in the CMI test) could cause the formation of NOR-HN<sub>2</sub>, showing a cytotoxicity directly proportional to the active terminal chlorine atoms (Fig. 1). On the other hand, the cytotoxicity could be increased *in vivo* as postulated by Foley *et al.*<sup>5</sup> with no relationship to an increase in reactive chloroethyl groups as measured by the NBP-TEA (Fig. 2).

A similar mechanism of action cannot be postulated for PAM. Following injection, there was a sharp decrease in reactive chloroethyl groups, but a thousand-fold increase in toxicity (Figs. 2 and 3). Linford<sup>7</sup> showed that the alkylation reaction between 'Chlorambucil' and serum proteins occurring *in vitro* was about 50 per cent complete in 12 h at 37° C. In our hands, the alkylation reaction between PAM and serum proteins occurring *in vivo* was complete in 30 min as evidenced by the negative results with the NBP-TEA test (Table 1). If PAM and 'Chlorambucil' can be considered to react in similar ways, the full recovery of PAM 30 min after injection by absorption measurements at 258 mμ can only mean that PAM was hydrolysed to a compound

with the same absorption maximum as PAM and to a compound which alkylates serum proteins within 30 min. Thus, the latter substance could conceivably be more cytotoxic than PAM itself. The rapid alkylation of PAM with serum proteins may not constitute a source of waste of administered drug as postulated by Linford for 'Chlorambucil', but rather provide a drug of considerably increased clinical value.

We thank Dr. R. J. Rutman, of the Department of Chemistry, University of Pennsylvania, for his assistance with this work.

## TAXONOMIC RELATION OF ERYTHROCYTE COUNT, MEAN CORPUSCULAR VOLUME, AND BODY-WEIGHT IN MAMMALS

By PAUL B. DUNAWAY and LOVELL L. LEWIS

Radiation Ecology Section, Health Physics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee

ERYTHROCYTE counts and sizes have been published<sup>1-3</sup> for many species of mammals, but, so far as we have been able to ascertain, a correlation of red blood cell count and mean corpuscular volume with taxonomic status of the various species has not been enunciated. Red blood cell count and mean corpuscular volume vary widely among vertebrates, but haematocrit percentages show relatively little variation<sup>3</sup>. It follows, of course, that if haematocrit percentages do not vary greatly, then red blood cell count and mean corpuscular volume must vary in relation to each other. The publications containing information about comparative haematology commonly present values for red blood cell count and cell size in various species of mammals without attempting to relate differences within or between taxa<sup>1-3</sup>. This article will discuss an intrafamily relation of erythrocyte number and mean corpuscular volume to body-weight.

Haematological investigations of the peripheral blood of native small mammals were initiated at Oak Ridge National Laboratory in order to establish baseline values before research was begun on the effects of ionizing radiation on the blood of mammals living in environments contaminated with radionuclides. Haematopoietic tissues are relatively radiosensitive<sup>4</sup>, and sampling of peripheral blood affords an opportunity to examine effects in blood without killing animals, which is of decided advantage in research concerned with population dynamics. In addition, haematology should be of considerable diagnostic value in detecting radiation-induced pathological conditions in other tissues in much the same way that clinical haematology is utilized<sup>5</sup>.

Most of the mammals sampled were from our laboratory colonies or were live-trapped during different seasons of the year on the U.S. Atomic Energy Commission reservation at Oak Ridge, Tennessee (Table 1). Mammals from other areas are listed in Table 2. Individuals were excluded if they exhibited pathological conditions known to cause

changes in the peripheral blood. The average weights listed for each species are for 'adult' and 'sub-adult' animals, because red blood cell count and haematocrit percentages are lower in very young mammals than in older mammals<sup>3,6</sup>.

Blood was taken by tail slice from the smaller rodents and from either the tail or an amputated toe of larger animals. Blood samples were extracted from shrews by cardiac puncture and from bats by amputation of a wing. Blood from all species was collected in 2-dram vials coated on the inside surface with ~1 mg of disodium ethylenediamine tetraacetate powder, which was used as an anticoagulant. A Coulter model B electronic particle counter was utilized to obtain red blood cell counts; counter error was <2 per cent. Haematocrit percentages were obtained with an International Micro-capillary centrifuge, model B, and reader, model CR. Haematological techniques adapted or developed during this work are described in detail elsewhere<sup>6</sup>.

The number of erythrocytes per mm<sup>3</sup> is inversely related to the body-weights of the species in each of the families listed in Table 1. Mean erythrocyte volume is directly related to body-weight within each rodent family examined. Erythrocyte number is plotted against body-weight in Fig. 1. Curves are provided only for the Cricetidae and Sciuridae since only two species are available in each of the other two families. However, it appears that, when more species of appropriate size in the Soricidae and Muridae are sampled, the resultant curves will not coincide with the curves for the cricetids and sciurids, at least in the region where the lightest species occur.

In the Cricetidae, rate of decrease in erythrocyte number is relatively rapid from *P. leucopus* to *S. hispidus* (Fig. 1). The flexions at each end of the sigmoid curve indicate that counts much greater than 12.5 cells × 10<sup>6</sup>/mm<sup>3</sup> or much less than 6.0 cells × 10<sup>6</sup>/mm<sup>3</sup> are not to be expected for members of the Cricetidae in the Oak Ridge area. Also,

\* Migratory species. † From elevation of  $\sim 8,000$  ft. ‡ From elevations ranging from 4,500 to 6,300 ft.

judging from the data of Table 1, it appears that mean corpuscular volume much greater than  $74 \mu^3$  or much less than  $38 \mu^3$  will not be found in this family. The rapid increase in mean corpuscular volume from *M. pinetorum* to *O. palustris* is interesting; in the transition from 'mouse size' to 'rat size' in this family it may be that the surface-to-volume ratio of the erythrocyte becomes less critical in the maintenance of blood equilibria.

The red blood cell values for the lightest sciurids are relatively high, in comparison with the cricetids, but it appears that when a more definitive curve can be drawn for this family, the curve will converge with, or cross

under, the curve for the cricetids in the area where the values for the heaviest species of these families are located. Similarly, mean corpuscular volume in the lightest sciurids is smaller than in cricetids of comparable weights, but the mean corpuscular volumes of *M. monax* and *O. zibethicus* are similar.

The rate of decrease for red blood cell count and the rate of increase for mean corpuscular volume may be relatively low in both the Muridae and Soricidae within the weight ranges spanned between the two species examined for each family. Actually, the differences between red blood cell count and mean corpuscular

Fig. 1. Relation of erythrocyte count to body-weight in the Soricidae, Sciuridae, Cricetidae, and Muridae of the Oak Ridge area

volume in the two shrews are not significant, and it may be that both these species are in the weight range where relatively little change in these values occurs in the Soricidae. The least shrew (*C. parva*), despite its name, is not the lightest soricid, and *B. brevicauda* qualifies only as a 'medium-sized' member of the family. Similarly, *M. musculus* is not the lightest murid, and *R. norvegicus* is not one of the heaviest. More species of appropriate weights in these families must be examined before more can be said as to the interrelation of red blood cell count, mean corpuscular volume, and weight.

Haematocrit percentages ranged from about 39 to 49 in the mammals represented in Table 1. There appeared to be a tendency for the lightest species of each family to have relatively high haematocrit percentages and for the heaviest species of each family to have relatively low percentages.

The effects of altitude on blood apparently vary according to the species of animal involved. Red cell counts and haematocrit percentages are increased in rabbits, dogs and sheep acclimated to high altitude, but blood counts in the vicuña (*Lama vicugna*) and the llama (*L. glama*) are much the same at sea-level and at high altitudes<sup>7</sup>. Kalabuchov<sup>8</sup> reported that the wood mouse (*Apodemus sylvaticus*) and the yellow-necked mouse (*A. flavicollis*) were able to increase the number of erythrocytes in response to decreased atmospheric pressure, but that the field mouse (*A. agrarius*), the bank vole (*Clethrionomys glareolus*), and the grey hamster (*Cricetulus migratorius*) were not able to do so. Furthermore, the red blood cell count in *A. sylvaticus* transferred from a mountain (1,600 m) to a plain (150 m) dropped only slightly after a month, and by two months was even slightly elevated over the previous value for the mice at the high altitude.

We sampled four species from relatively high altitudes (Table 2). The erythrocyte count of the *E. minimus* after one month at a low altitude may have been temporarily depressed, as found by Kalabuchov<sup>8</sup> for *A. sylvaticus*, because the count of each *E. minimus* increased after three months. The *T. hudsonicus* from the Smoky Mountains had to be returned immediately because of an agreement with the U.S. National Park Service, but it is evident the red blood cell count for these squirrels was

considerably higher than the red blood cell-weight curve for sciurids on the Oak Ridge area (Fig. 1). The count for each *P. maniculatus* after two months at the low elevation increased at least a million over the count two days after removal. Of the eight *C. gapperi* sampled two days after removal, four died within one month. Satisfactory blood samples were taken from only two of the surviving four mice at one month; but the count for each was more than one million higher than the highest count recorded for any of the eight animals sampled two days after removal from the high altitude. However, the counts after two months for three of the *C. gapperi* were similar to the values for the eight mice two days after removal.

It seems that *E. minimus*, *T. hudsonicus*, *P. maniculatus*, and *C. gapperi* may be examples of species which possess the capacity to withstand relatively great changes of oxygen pressures. Hall<sup>9</sup> proposed the term 'eurybaric' for such species and 'stenobaric' for those species that are incapable of adjusting to great differences in altitude. Kalabuchov<sup>8</sup> speculated that the degree of plasticity as regards physiological adjustment to changes in altitude may be an important factor in the vertical distribution of mammals.

Latitude, as well as altitude, may be important in considerations of comparative haematology. The *T. hudsonicus* from Alaska, *S. niger* from Michigan, and the *M. pennsylvanicus* from Virginia had higher red blood cell counts than might be expected from the red blood cell-weight curves for the respective families in the Oak Ridge area (Fig. 1). Furthermore, the counts for the *B. taylori* from Texas, *P. polionotus* from Georgia, and *N. alleni* from Florida were lower than might be expected for similarly-sized cricetids in the Oak Ridge area. The values for the Alaska *T. hudsonicus* and the Florida *N. alleni* are particularly interesting. The average red blood cell count for the Alaska *T. hudsonicus* at first sampling was more than two million higher (18 per cent) than the count for the Smoky Mountain squirrels in spite of the fact that the latter were from an altitude of from 4,500 to 6,300 ft. and the former were living at a low altitude (~450 ft.). The average red blood cell value for the *N. alleni* at first sampling was about one million less than for the red blood cell count for the *O. zibethicus*, which weighed more than five times as much as its smaller relative. It may be seen that the erythrocyte count decreased in the Alaska *T. hudsonicus* and increased in the *N. alleni* while these animals were in our laboratory.

The red blood cell and mean corpuscular volume values for the *S. hispidus* from both Texas and Georgia are very similar to the counts for the local cotton rats. This species apparently has extended its geographical range in the central part of the United States northward within a relatively short time. For example, Cockrum<sup>10</sup> estimated that this rat extended its range about 100 miles northward in Kansas during 1933-47. Perhaps the northward movement of this species has been too rapid for evolution of the haematopoietic system to 'keep pace'.

Two species did not fit into this theory of a taxonomic relation of red blood cell count and mean corpuscular volume to body-weight. The *N. floridana* from a valley in the Cumberland Mountains were trapped only about 20 miles west of Oak Ridge, and the elevation was almost exactly the same. However, the red blood cell count for these wood rats and the ones from Virginia was almost a million higher than for the *S. hispidus*, which weighed only about one-third or one-fourth as much as the *N. floridana*. Perhaps other species in the genus *Neotoma* (particularly in the sub-genera *Teonoma*, *Hodomys* and *Teanopus*) should be examined in order to ascertain whether high red blood cell count and small cell size are peculiar only to *N. floridana* (and perhaps closely related species) or are characteristic of the entire genus. Erythrocyte count of the *E. fuscus* was less than that of the lighter *P. subflavus*, but the *L. borealis*, almost twice as heavy

as the *P. subflavus*, exhibited red blood cell counts more than five million more than for the smaller bat. The *L. borealis* is a migratory bat; *E. fuscus* and *P. subflavus* hibernate in caves or similar shelters. During favourable weather, all three species feed at night; but during the day *L. borealis* hangs in trees and the other two species retire to protected sites. It is obvious that bats which take refuge in trees and similarly exposed places must be subjected to greater vicissitudes of weather than are bats that live in the equable environment of such places as caves. Perhaps the haematopoietic system of *L. borealis* has evolved to meet the severe metabolic demands that must arise at times, particularly during cold weather and migration. However, the changes in the peripheral blood of bats induced by daily torpor or winter hibernation probably should be examined in detail before evaluation of normal values is attempted.

Inspection of the literature indicates that a relation between red blood cell count, mean corpuscular volume, and size of mammal may exist in families other than those discussed in this article. For example, Ponder *et al.*<sup>10</sup> examined the blood of captive camelids and reported red blood cell counts (cells  $\times 10^6/\text{mm}^3$ ) of 19.40 for the alpaca (*Lama pacos*), 11.30 for the llama (*Lama glama*), 10.80 for the Arabian camel (*Camelus dromedarius*), and 10.45 for the Bactrian camel (*Camelus bactriens*). Average erythrocyte counts (cells  $\times 10^6/\text{mm}^3$ ) have been summarized<sup>3</sup> for bovids such as domesticated goats (16.0), sheep (10.3), and cattle (8.1). Gulliver, in his intensive examination of the sizes (diameters) and shapes of red blood cells of vertebrates<sup>11</sup>, concluded that, within an order or even some families of mammals, erythrocytes with the greatest diameters were found in large species and the smallest cells in small species. On the other hand Emmons wrote: "What determines the size of the red cell for different species of mammals is yet unknown; certainly there is no relation between the size of the animal and that of its erythrocyte"<sup>12</sup>.

Several writers have touched on haematological and physiological aspects that may be involved in a taxonomic interrelation between animal size and erythrocyte number, shape and size. Gulliver was interested in the sizes of red corpuscles in relation to taxonomy, as discussed earlier, but he speculated also on the possible physiological significance of the different sizes and number of these cells in the various species<sup>11</sup>. Wintrobe stated: "Differences in number, size, and morphology of the red

blood corpuscles of the lower vertebrates and those of the mammalia furnish further evidence of the efficiency attained through the evolutionary process"<sup>3</sup>. Jordan suggests that, in general, erythrocyte count, size and shape are related to the metabolism of animals<sup>13</sup>. It has been demonstrated that metabolic rate is inversely related to the size of mammal<sup>14-16</sup>. Consequently, if metabolic rate is related to size of mammal, if red blood cell number and size are related to metabolism, and if erythropoietic systems have evolved along diverging lines, it seems likely that correlations between red blood cell count, mean corpuscular volume, and species weights also may exist (but at differing rates) throughout the various natural taxa of the Mammalia.

## VISUAL RECEPTOR POTENTIAL OBSERVED AT SUB-ZERO TEMPERATURES

By DR. WILLIAM L. PAK\* and THOMAS G. EBREY

Department of Biophysics, University of Chicago

THE recent discovery of the early receptor potential in the eye of the Cynomolgus monkey by Brown and Murakami<sup>1</sup> seems to provide a very useful system for the examination of visual excitation. The latency of the early receptor potential is extremely short<sup>1,2</sup> and, as Cone<sup>3</sup> has shown, the amplitude of the signal is linear with respect to the amount of rhodopsin bleached, strongly suggesting that the early receptor potential is closely linked to the initial events in the bleaching of rhodopsin. Since then it has been shown that the early receptor potential consists of two independent receptor potentials, the positive peak and the negative peak<sup>3</sup>. The positive peak has the shortest latency of all known receptor potentials<sup>3</sup>, and its extraordinary resistance to cooling<sup>3</sup> seems to open up a new avenue of approach in visual excitation research. In order to establish the

relationship between the positive peak and visual excitation, it is important to ask by what mechanism the positive peak is generated. Elucidation of this question will probably have important consequences in the understanding of visual excitation itself. Moreover, it is not unlikely that the positive peak is generated by one of the initial steps of visual excitation. The question before us is, then, at what stage in the bleaching of rhodopsin does the generation of the positive peak occur?

As is well known, the bleaching of rhodopsin to a mixture of all-trans retinal and opsin proceeds over several transient intermediates in the following sequence: pre-lumirhodopsin, lumirhodopsin, metarhodopsin I, and metarhodopsin II<sup>4-6</sup>. Presumably the initial step, rhodopsin  $\rightarrow$  pre-lumirhodopsin, results from the photoisomerization of the 11-cis retinal to all-trans<sup>4,7</sup>. All the other steps are thermal, dark reactions which follow as a consequence of this initial, photochemical event<sup>8</sup>. All

\* On leave from the Department of Physics, Stevens Institute of Technology, Hoboken, New Jersey.

these transient intermediates can be stabilized by cooling<sup>4</sup>. Cattle pre-lumirhodopsin in solutions is stable below about  $-140^{\circ}\text{C}$  (refs. 4 and 7), and lumirhodopsin and metarhodopsin I, below about  $-40^{\circ}\text{C}$  and  $-15^{\circ}$  to  $-20^{\circ}\text{C}$ , respectively<sup>5,6,8,9</sup>.

Wald and his colleagues have long felt that the hydrolysis of metarhodopsin to retinal and opsin is much too slow a process to have a direct role in visual excitation<sup>4,5,8,10,11</sup>. On the other hand, Hagins<sup>12</sup> showed that a process strongly suggestive of the hydrolysis of metarhodopsin occurs in rabbit eyes long before the electroretinographic response to the stimulus flash can be recorded. He therefore concluded that the release of retinal from opsin may well be responsible for the excitation. Abrahamson *et al.*<sup>13</sup> have also concluded that not only is the bleaching of metarhodopsin fast enough to be involved in the excitatory process but is likely to be so because of the large positive changes of entropy involved in this step. In the light of the recent evidence that the absorption spectrum of metarhodopsin II is very similar to that of retinal and opsin, what these workers observed may have been the conversion of metarhodopsin I to II rather than the hydrolysis of metarhodopsin II (ref. 6). Although the hydrolysis of metarhodopsin II is a slow process, the transformation of metarhodopsin I to II is likely to be very rapid at the physiological temperature<sup>6</sup>. Thus, even if the hydrolysis of metarhodopsin II were to be excluded from considerations of speed, the reaction, metarhodopsin I  $\rightarrow$  II, cannot be discarded *a priori* as a possible source of excitation.

As the foregoing discussion suggests, pertinent information relating to the question of visual excitation is still rather scarce. In the work recorded here we sought to localize the step or steps in the bleaching of rhodopsin which might be responsible for the production of the positive peak of the early receptor potential. Our technique has been to observe the behaviour of the positive peak in the excised eye of the albino rat at low temperatures at which one or more of the transient stages in the bleaching of rhodopsin is known to be stable.

The essential elements of the experimental arrangement are similar to those described previously<sup>2,3</sup>. The positive peak of the early receptor potential was observed in the electroretinogram (ERG) elicited from the excised eye of the albino rat using a 65-joule strobe lamp having less than a 0.7-msec flash duration. Unlike the later retinal potentials the early receptor potential displays an extraordinary resistance to anoxia<sup>1-3</sup>. Therefore, the positive peak of the early receptor potential could be investigated on excised eyes, making it relatively simple to vary the temperature of the eyes. On the other hand, since the visual pigment does not regenerate in the excised rat eyes, each set of observations had to be made on a freshly excised, fully dark-adapted eye. The electrodes consisted of cotton wicks leading to silver wires coated with silver chloride. The cotton wicks were soaked in a 2:1 mixture of glycerol and saline to prevent them from freezing and to help maintain good contact with the eye at low temperatures while retaining their conductivity. In order to minimize artefacts the electrodes were carefully shielded from the flash, exposing only the tips of the cotton wicks, the strobe lamp was housed in a soft steel box, and the entire equipment was housed in an electrostatically shielded cage. The remaining artefacts were negligible during the time-interval of interest. The eye could be kept at any selected temperature by placing it on top of a small copper cylinder, kept partly submerged in a thermal bath. The thermal bath consisted of an aqueous solution of calcium chloride maintained at its freezing temperature by adding dry ice. The temperature of the bath was varied by changing the calcium chloride concentration.

All the work recorded here was carried out at temperatures below about  $5^{\circ}\text{C}$ . We have previously reported<sup>3</sup> that the positive peak could be observed at temperatures

Fig. 1. Dependence on temperature of the positive peak of the early receptor potential. The positive peak of the early receptor potential observed in the ERG of the dark-adapted albino rat at various temperatures: a,  $0^{\circ}\text{C}$ ; b,  $-10^{\circ}\text{C}$ ; c,  $-20^{\circ}\text{C}$ .

as low as  $-10^{\circ}\text{C}$ . We have now extended the measurements to about  $-35^{\circ}\text{C}$ . The positive peak can still be seen at this low temperature. The signals observed at  $0^{\circ}$ ,  $-10^{\circ}$ , and  $-20^{\circ}\text{C}$  are presented in Figs. 1a, 1b and 1c, respectively. Although the signal amplitudes vary from one eye to another, there is a general tendency for the amplitude to decrease with lowering of temperature. At  $0^{\circ}\text{C}$  the amplitude of the positive peak varies roughly between  $300\ \mu\text{V}$  and  $500\ \mu\text{V}$ , and, at  $-15^{\circ}\text{C}$ , between  $100\ \mu\text{V}$  and  $300\ \mu\text{V}$ . The signals obtained at  $-35^{\circ}\text{C}$  varied between  $50\ \mu\text{V}$  and  $100\ \mu\text{V}$ .

As may be seen in Fig. 1, the amplitude maximum of the signal shifts to later and later times as the temperature is lowered. We have measured the time-interval between the start of the flash and the arrival of the amplitude maximum of the signal (peak time) at five different temperatures,  $5^{\circ}$ ,  $0^{\circ}$ ,  $-5^{\circ}$ ,  $-10^{\circ}$  and  $-15^{\circ}\text{C}$ . At  $5^{\circ}\text{C}$  the amplitude maximum is reached in about 0.4 msec, and at  $-15^{\circ}\text{C}$  the peak arrives in about 3.3 msec, giving a temperature coefficient ( $Q_{10}$ ) of about 3.

Since the duration of the stimulus flash is about 0.7 msec, there is a considerable temporal overlap between the flash and the observed response, particularly at  $0^{\circ}$  and  $5^{\circ}\text{C}$ . Therefore, the shape of the leading edge of the positive peak is probably modulated by the shape of the stimulus flash. For this reason no attempt was made to calculate the rate constants from the shape of the signal; rather, the reciprocal of the peak time was taken as a measure of the rate of the production of the positive peak. The results are shown in Fig. 2 as an Arrhenius plot. As may be seen in Fig. 2, the experimental points fall on a straight line with very good accuracy, yielding an activation energy of  $16 \pm 3\ \text{kcal/mole}$ .

As the temperature is lowered, the resistance of the cotton wick electrodes is expected to change, and possibly contact resistances and stray capacitances and inductances may change. We have investigated the possible effects of the electrodes on the measured temperature dependence of the peak time. A small piece of metal was put in contact with electrodes instead of the eye deliberately to produce a measurable photo-artefact. The time of the arrival of the peak of the artefact was measured as a function of temperature. Although the peak time of the artefact

Fig. 2. Arrhenius plot of the rate of production of the positive peak. The reciprocal of the peak time of the positive peak was taken as a measure of the rate of production of the positive peak to cast the experimental points in the form of an Arrhenius plot. The peak times are expressed in msec

does change slightly with temperature, the effect is small, the temperature coefficient ( $Q_{10}$ ) being only about 1.3. If this correction is applied, we would obtain for the temperature coefficient of the positive peak a value of about 2.4, corresponding to an activation energy of about 13 kcal/mole.

The latency of the initial rise toward the positive peak is obscured by the artefacts but has been estimated to be less than 50  $\mu$ sec at 0° C. An approximate estimate of the latency at -20° C is still only about 100  $\mu$ sec.

The results of our work exclude almost conclusively the transformation of metarhodopsin I to II, the hydrolysis of metarhodopsin II, or the photo-conversion of rhodopsin to pre-lumirhodopsin as a possible mechanism for the generation of the positive peak.

Let us first consider the time-sequence of the bleaching of metarhodopsin. Probably the shortest decay time of metarhodopsin reported is due to Hagins<sup>12</sup>. In his experiments with excised rabbit eyes he estimated the half-time of decay of metarhodopsin at the physiological temperature to be about 120  $\mu$ sec. In the rat both the positive and negative peaks of the early receptor potential begin to appear long before 120  $\mu$ sec at the physiological temperature. The latency of the positive peak is less than 50  $\mu$ sec at 0° C (ref. 3) and only about 100  $\mu$ sec at -20° C. If Hagins's values for the half-time of decay of metarhodopsin at 12° and 26° C were to be extrapolated to 0° and -20° C, one would obtain about 300 msec and 70 sec, respectively. Clearly the positive peak of the early receptor potential must occur long before the decay of metarhodopsin observed by Hagins.

Furthermore, in solutions cattle metarhodopsin I goes over to metarhodopsin II with a half-time of about 1 min at 1° C and about 100 min at -9° C (ref. 6). Again this is much too slow a process to account for the production of the positive peak.

The observed temperature dependence of the rate of production of the positive peak also indicates that the process which converts metarhodopsin I to II is not responsible for the generation of the positive peak. In their investigation with cattle rhodopsin in solutions

Matthews *et al.*<sup>8</sup> obtained a temperature coefficient ( $Q_{10}$ ) of about 100 for the step going from metarhodopsin I to II. The decay of metarhodopsin Hagins examined in the intact rabbit eyes also shows a considerable temperature dependence. From his results the temperature coefficient ( $Q_{10}$ ) can be calculated to be about 8. These values are much too large to be consistent with the value,  $Q_{10} \approx 3$  we obtain for the positive peak.

Perhaps the most crucial piece of evidence we can present for rejecting the possible involvement of the decay or hydrolysis of metarhodopsin in the production of the positive peak is that the positive peak can be observed in the rat at -35° C, at which temperature both metarhodopsin I and II are known to be stable. Cattle metarhodopsin I in solutions is stable up to about -20° to -15° C (refs. 5 and 6), and metarhodopsin II remains stable up to somewhat higher temperatures<sup>6,7</sup>. Therefore, the production of the positive peak, in all probability, precedes both the decay and the hydrolysis of metarhodopsin. If the positive peak is, indeed, produced by one of the early steps of visual excitation, the fact that the production of the positive peak precedes the decay or hydrolysis of metarhodopsin would suggest that the visual excitation itself precedes these steps.

Finally, our investigation of the dependence on temperature of the peak time of the positive peak shows that the positive peak probably is not produced directly by the initial photo-isomerization of the 11-*cis* retinal to all-*trans*. The rate of formation of the positive peak, as indicated by the reciprocal of the peak time, changes by a factor of about 3 in a temperature variation of 10° C. Since the initial photo-excitation of rhodopsin requires photons of several eV, a temperature variation of 10° C (about 10<sup>-3</sup> eV) should have only a negligible effect on the rate of photo-isomerization. The fact that the rate of formation of the positive peak is sensitive to a small variation in temperature indicates that a temperature sensitive process intervenes between the action of the light on the visual pigment and the generation of the positive peak. Since the photo-isomerization of the 11-*cis* retinal to all-*trans* is thought to be represented by the step going from rhodopsin to pre-lumirhodopsin, this step is not likely to be the rate-determining step in the production of the positive peak.

We therefore conclude that the generation of the positive peak, in all likelihood, occurs after the photo-isomerization of the retinal has already taken place but before either metarhodopsin I can decay into metarhodopsin II or metarhodopsin II can hydrolyse into retinal and opsin. Thus the generation of the positive peak probably takes place at some step intermediate between pre-lumirhodopsin and metarhodopsin I.

## RADIO ASTRONOMY

## A New Class of Radio Source Spectra

THE flux densities of 35 non-thermal radio sources were measured at 8,000 Mc/s ( $\lambda$  3.75 cm) with the University of Michigan's 85-ft. reflector. Comparison of these measurements with the spectra of the sources at frequencies less than 3,200 Mc/s (ref. 1) showed that most spectra were either straight (constant spectral index) or curved downward (steepening spectrum) at the high-frequency end of the spectrum. However, the radio source 3C 84 which has been identified with the Seyfert galaxy NGC 1275 (refs. 2 and 3) was found to have a flux density at 8,000 Mc/s which was four times greater than that expected from a straight line extrapolation of the spectrum observed at frequencies less than 3,200 Mc/s. This is the first reported instance of a radio spectrum having such a pronounced upward turn in its spectrum with increasing frequency. (The novel spectrum of NGC 1275 was first reported by us at the International Scientific Radio Union General Assembly in Tokyo, September 9-20, 1963.) Thus NGC 1275 may represent a new class of radio source spectra. The radio source 3C 279 was also investigated because a pronounced upward turn of its spectrum was predicted by J. A. Roberts from measurements up to 2,650 Mc/s; we found its spectrum to be similar to NGC 1275. A third source 3C 273 has a spectral flattening at the high frequency end, but does not have a positive spectral index as do the foregoing two sources.

In order to confirm the upward (positive) curvature in the spectra of these sources at centimetre wave-lengths, flux density measurements were also made at 16,500 Mc/s ( $\lambda$  1.82 cm). Table 1 lists the measured flux densities and their standard deviations of NGC 1275, 3C 279, and 3C 273 at 8,000 Mc/s and 16,500 Mc/s along with the flux density measurements of Virgo A, Taurus A, and Cassiopeia A which are given for reference. All these sources were found to be within 1 min of arc of their expected positions.

In these measurements account has been taken of the finite angular size of the source, the variation of the antenna gain with zenith angle, a small daily antenna gain variation, atmospheric extinction, and the measured linear polarization of the sources<sup>4</sup>. The flux density calibration was made relative to an absolute flux density measurement of Taurus A at 9,400 Mc/s (ref. 5), assuming a spectral index of  $-0.26$ . Fig. 1 shows the spectra of NGC 1275, 3C 279, 3C 273, and Virgo A extended to 8,000 Mc/s and 16,500 Mc/s from measurements made at frequencies less than 3,200 Mc/s (refs. 1 and 6). The ordinate of each spectrum has been arbitrarily displaced to give a compact presentation.

The low-frequency spectrum of NGC 1275 has been discussed by several authors<sup>7-9</sup>. Baars, Mezger and Wendker<sup>10</sup> have recently made flux density measurements of NGC 1275 at five frequencies including 5,000 Mc/s and 14,500 Mc/s. Their observations confirm the upward turn in the spectrum of NGC 1275 reported here.

Table 1. MEASURED FLUX DENSITIES AT 8,000 Mc/s AND 16,500 Mc/s

Source designation	Flux density and standard deviation in units of $10^{-26}$ W m <sup>-2</sup> (c/s) <sup>-1</sup> (Epoch 1964-C)	
	8,000 Mc/s	16,500 Mc/s
NGC 1275 or 3C 84	$18.8 \pm 1.0$	$23.6 \pm 2.5$
3C 279	$15.6 \pm 0.8$	$15.4 \pm 1.5$
3C 273	$26.9 \pm 1.3$	$23.3 \pm 2.0$
Virgo A	$45.0 \pm 2.7$	$26.7 \pm 4.2$
Taurus A	$570 \pm 28$	$477 \pm 44$
Cassiopeia A	$580 \pm 29$	$332 \pm 27$

A flux density of NGC 1275 at 8,000 Mc/s was published by Heesch<sup>11</sup>, but the pronounced upward curvature in the spectrum was not found due to the inaccuracy of his measurement. We find an abrupt change in the spectral index from  $-0.67$  below 3,200 Mc/s to  $+0.84$  between 3,200 Mc/s and 8,000 Mc/s. Such a large positive spectral index cannot be produced by synchrotron radiation from any energy distribution of relativistic electrons when absorption processes are not present.

If the low-frequency spectrum of NGC 1275 is linearly extrapolated to high frequencies and subtracted from the observed composite spectrum in Fig. 1, an isolated spectrum of a high-frequency component of the source is presumably obtained (Fig. 2). This spectrum has a spectral index of about  $+2$  at frequencies less than 8,000 Mc/s and is nearly flat at frequencies greater than 8,000 Mc/s. Although models can be made involving absorption of a synchrotron spectrum, this spectrum could be produced by thermal radiation of free-free transitions in a region of ionized hydrogen that becomes opaque near 8,000 Mc/s. The angular diameter of the high-frequency spectral component of NGC 1275 has not been measured. An upper limit of  $90''$  of arc can be inferred from our measurements. If we assume that the diameter of the high-frequency component is  $10''$  of arc, the same as the low-frequency spectral component<sup>12</sup>, and that the high-frequency component is a thermal source with some unknown ionization process, then the electron temperature,  $T_e$ , of the gas is  $4,500^\circ$  K. If the source, at a

Fig. 1. The high-frequency radio spectra of four sources showing the novel spectral features at 8,000 Mc/s and 16,500 Mc/s of NGC 1275 and 3C 279 in contrast to the normal non-thermal spectrum of Virgo A. The ordinate of each spectrum has been arbitrarily displaced

Fig. 2. The observed spectrum of NGC 1275 showing a possible separation into high- and low-frequency spectral components

distance of 54 Mpc (ref. 13), consists of a uniform spherical distribution of thermal electrons, then the electron density is  $170 \text{ cm}^{-3}$  and the total mass,  $M$ , is  $4 \times 10^{10} M_{\odot}$  (about one-tenth the mass of the galaxy). The source is 2,600 parsecs in diameter, presumably located at the centre of the 30 kpc diameter galaxy. It should be noted that the values of the above parameters are sensitive to the adopted angular diameter,  $\phi$ , and the distance,  $R$ , of the source:  $T_e \propto \phi^{-2}$  and  $M \propto R^{-2.5} \phi$ .

The fact that the high-frequency component of NGC 1275 appears to be partially polarized at 8,000 Mc/s (ref. 4) is not evidence against the thermal model since the degree of polarization obtained,  $0.5 \pm 0.4$  per cent, is at the threshold of detection and, in any event, may be attributed to the low-frequency component of the source.

The predicted free-free and Paschen continua at optical frequencies from the above thermal model is not inconsistent with the optical magnitude of the galaxy. However, on the basis of a photographic estimate by Seyfert<sup>14</sup> the integrated flux density of the  $H_{\beta}$  line is a few orders of magnitude less than the  $4 \times 10^{-12} \text{ W m}^{-2}$  predicted for the hydrogen recombination spectrum of the foregoing model. The ratio  $(\lambda 5007 + \lambda 4959)/\lambda 4363$  of [OIII] (ref. 14) is 8.8 in NGC 1275 compared with about 120 in planetary nebulae. An electron density of  $10^7 \text{ cm}^{-3}$  assuming  $T_e \sim 10^4 \text{ }^{\circ}\text{K}$  is required to produce such a ratio by collisional excitation.

The foregoing observed value of the [OIII] line ratio can be made consistent with a thermal interpretation of the radio spectrum on NGC 1275 if  $T_e$  is  $1.5 \times 10^6 \text{ }^{\circ}\text{K}$  and  $N_e$  equals  $6 \times 10^4 \text{ cm}^{-3}$ . To fit the opaque portion of the thermal radio spectrum the diameter of the radio source must be  $0.54''$  or 136 parsecs. The corresponding total mass of ionized hydrogen is  $2 \times 10^9 M_{\odot}$ , which is substantially lower than obtained in the first model. The predicted  $H_{\beta}$  flux in the second model is about  $10^{-13} \text{ W m}^{-2}$  and is within about an order of magnitude of existing optical data<sup>14</sup>. We feel that the value of  $1.5 \times 10^6 \text{ }^{\circ}\text{K}$  for the electron temperature may not be unreasonably high in view of the unusual optical spectrum and fragmented appearance of the galaxy.

Photoelectric measurements of the  $H_{\beta}$  flux of the nucleus of NGC 1275 and future angular diameter measurements of the radio source at frequencies greater than 8,000 Mc/s will be able to test the above two models.

It is also possible that the high-frequency component of NGC 1275 is produced by a relatively flat synchrotron radiation spectrum similar to that of 3C 273B but with a low-frequency spectral cut-off near 8,000 Mc/s due to self-absorption. In this case the spectral index below this frequency would be  $+2.5$ , and this is not inconsistent with the observations. However, synchrotron self-absorption at this high frequency requires exceptionally large magnetic fields; greater than 1,000 gauss if the radio source is larger than 1 parsec in diameter.

Little is known about the radio source 3C 279 since it has not been optically identified. If the high and low

frequency spectral components are separated as was done for NGC 1275, then the spectrum of the high-frequency component is also found to have a thermal-type radio spectrum. A  $10''$  of arc angular diameter for this component of 3C 279 would be required if the electron temperature is  $10^4 \text{ }^{\circ}\text{K}$  and the source is a thermally emitting ionized gas. Angular diameter measurements have been reported for the low-frequency component only:  $20''$  at 158 Mc/s (ref. 15) and less than  $36''$  at 960 Mc/s (ref. 16).

The radio source 3C 273 has been shown<sup>17</sup> to consist of two radio components separated by  $20''$  of arc. Component A, identified optically with a jet of emission<sup>18</sup>, has a steep non-thermal spectrum similar to Virgo A. Component B, identified with a quasi-stellar radio source<sup>18</sup>, has a nearly flat spectrum. The ratios of the flux densities of each component are such that the steep spectrum of component A dominates the observed composite spectrum at frequencies below 1,000 Mc/s while the nearly flat spectrum of component B contributes principally to the total flux density at frequencies greater than 1,000 Mc/s. This difference in the spectral index of each component can explain the positive curvature of the composite spectrum over the frequency range of observations, 178 Mc/s to 16,500 Mc/s.

## A Radio Investigation of NGC 1265 and NGC 1275

Dent and Haddock<sup>1</sup> have investigated the high-frequency part of the NGC 1275 spectrum and found that the flux density increases between 3 and 10 GHz by about a factor of two.

Earlier low-frequency flux density measurements of NGC 1275 are obscured by the fact that another radio source, NGC 1265, is spaced only half a degree from NGC 1275. Lynds and Sobieski<sup>2</sup> took a mean value of the flux density ratio of NGC 1275 and NGC 1265, measured by Leslie and Elmore<sup>3</sup> at 178 MHz, and their own ratio at 3 GHz to separate the flux densities at intermediate frequencies measured with telescopes of low angular resolution.

Present-day instrumental facilities allow the removal of uncertainties in this method by direct measurement. In order to separate the flux densities of NGC 1265 and NGC 1275 below 3 GHz and to check the feature found by Dent and Haddock<sup>1</sup> in the high-frequency region, we present here a set of new flux-density measurements of both sources. At the frequencies 750 MHz and 1410

MHz, the National Radio Astronomy Observatory (NRAO) 300-ft. telescope was used; at 2.7 GHz, 5 GHz and 14.5 GHz we used the NRAO 85-ft. telescope. The angular resolution of the telescopes is in each case high enough to allow a clear separation of the flux densities of both sources. The flux densities were measured relative to either Cassiopeia A, Taurus A or Virgo A, whichever was more convenient for a particular observation. Some earlier measurements at high frequencies<sup>1,2,4</sup> and the interferometer measurement by Leslie and Elsmore<sup>3</sup> were combined with our own measurements. All these observations also give a clear separation between NGC 1265 and NGC 1275. Our recently analysed high-frequency spectra of the strongest non-thermal radio sources<sup>5</sup> were used to convert the relative flux density measurements into flux densities. The flux densities used for the spectra of NGC 1265 and NGC 1275 are given in Table 1.

Frequency (MHz)	NGC 1275	NGC 1265	Ref.
178	41.0 ± 10% (m.e.)	15.5 ± 12% (m.e.)	3
750	22.9 ± 7.5%	11.5 ± 10%	—
1,400	13.0 ± 12%	6.3 ± 15%	—
2,700	8.7 ± 5%	—	—
3,000	8.7 ± 5.3%	3.7 ± 11%	2
3,000	8.9 ± 5.8%	—	4
5,000	10.7 ± 10%	< 2.5	1
8,000	18.8 ± 5%	—	—
14,500	18.2 ± 12%	—	—
16,500	23.6 ± 9%	—	1

The values are also shown in Fig. 1. The mean errors of the individual measurements are indicated by error bars. The spectrum of both sources steepens between 178 MHz and 3 GHz. But whereas the flux density of NGC 1265 is below our detection limit at 5 GHz, the spectrum of NGC 1275 shows the already mentioned increasing flux density above 3 GHz. This behaviour of the high-frequency part of the NGC 1275 spectrum has been discussed extensively by Dent and Haddock<sup>1</sup>.

Fig. 1. Spectra of NGC 1275 and NGC 1265

As NGC 1275 is classified as a Seyfert galaxy, we have looked at the other Seyfert galaxies at 5 GHz and 14.5 GHz. In all cases the results were negative. Our detection limit was 5 f.u. and 20 f.u., respectively.

## PHYSICS

### The Linear Temperature Scale

THE Kelvin temperature scale used at present is linear, forming an ordered sequence of numbers:

$$+ 0^\circ \text{K} \dots 273.16^\circ \text{K} \dots + \infty^\circ \text{K} \quad (1)$$

for all normal thermodynamic states. If the so-called 'abnormal' thermodynamic states are admitted, the foregoing thermodynamic scale can be extended by adding a sequence of negative temperatures<sup>1,2</sup>. Alternatively, if the following relation is introduced:

$$T = e^\psi \quad (2)$$

where  $\psi = \int g(\theta) d\theta$  and depends on the thermal properties ( $\theta$ ) of the system (refs. 3, 4, 5);  $T$ , absolute temperature ( $^\circ\text{K}$ ); it is possible to construct another temperature scale, the  $\psi$ -scale, or the logarithmic scale. Fig. 1 shows the relation between both these temperature scales.

Fig. 1. Relation between temperature scales

The logarithmic nature of the  $\psi$ -function assures that the zero value on the linear absolute scale ( $T$ -scale) will be reached asymptotically, that is,  $T = 0^\circ \text{K}$ , when  $\psi = -\infty$ .

Comparing both these scales (the linear scale and its explicit<sup>4,5</sup> functional form, the  $\psi$ -scale), the inaccessibility of the absolute zero<sup>6,7</sup> follows generically, being not imaginable from the linear  $T$ -scale alone.

## METEOROLOGY

### An Experimental Determination of the Atmospheric Temperature Profile by Indirect Means

AN article by Kaplan<sup>1</sup> suggested a method of obtaining indirectly the temperature profile of the atmosphere by measuring from a satellite the radiances at several wavelengths in the 15- $\mu$  band of carbon dioxide. To test the practical application of this proposal the U.S. Weather Bureau has developed a grating spectrometer<sup>2</sup> with fixed exit slits and detectors to measure simultaneously the

radiances in 5  $\text{cm}^{-1}$  intervals centred at 669, 677.5, 691, 697, 703 and 709  $\text{cm}^{-1}$  and a 7  $\text{cm}^{-1}$  interval centred at 899  $\text{cm}^{-1}$ .

A 3.2 million cubic ft. balloon ('Dacron-mylar' scrim) carrying the spectrometer was flown by the National Scientific Balloon Flight Station of N.C.A.R. at Palestine, Texas, during the daylight hours of September 11, 1964. The instrument, which has a viewing angle of  $12^\circ$ , was pointed vertically downward, and measured the differences between the atmospheric radiances and those from a 77° K black body.

The balloon reached a maximum altitude of 103,000 ft. and remained above 100,000 ft. for 7.5 h. At the beginning of the flight and at its termination 250 miles to the west, the sky was cloudless in the field of view. Through most of the day there were cumulus clouds, and at one time the balloon passed over a squall area which had clouds extending to about 35,000 ft. and which completely filled the field of view of the spectrometer. The digitized measurements were transmitted by a telemetry-command system furnished by the N.C.A.R. We believe that the flight data were accurate to better than 0.5  $\text{erg/cm}^2 \text{ sec strdn cm}^{-1}$  (about 1 per cent of the signals).

Fundamental to the determination of the temperature profile is an accurate knowledge of the atmospheric transmittance by carbon dioxide in each of the spectral intervals. These were calculated from theory and from parameters determined experimentally in our laboratory, and from the well-supported assumption<sup>3</sup> that carbon dioxide is uniformly mixed in the atmosphere at about 0.031 per cent by volume. It is also vital that the layers of the atmosphere contributing in the various spectral intervals overlap to a considerable extent; but it is likewise important to the stability of the solution that a significant degree of independence remains.

The set of simultaneous equations expressing the measurements in terms of the integral form of the radiative transfer equation may be linearized. Using a minimization technique developed by our group this set may be solved to give the vertical temperature profile.

Fig. 1. Temperature profile from radiosondes (dotted line), connected line segment series solution (solid line), trigonometric series solution (dashed line) from data taken with no clouds in the spectrometer's field of view.

Fig. 2. Temperature profile from radiosondes later in the day (dotted line), connected line segment series solution (solid line) from data taken with clouds filling the instrument's field.

Because of an uncertainty concerning the calibration of the 669  $\text{cm}^{-1}$  flight data they were not used in the calculations; we would expect the inversion of the integral equation to result in a more stable and accurate solution if all six spectral intervals had been used. Results of our computations using only five intervals are shown in Figs. 1 and 2.

Fig. 1 shows the temperature profile determined from radiosonde data (dotted line) early in the flight, when the sky was clear and the entire atmosphere below the instrument contributed to the radiances. Two solutions are given: a series of connected line segments (solid line); and a trigonometric series (dashed line). Each of these two solutions has advantages and disadvantages. The trigonometric series is free to choose levels where changes of slope occur; but it cannot follow sharp changes in slope. The line segments can follow slope discontinuities, but the end points cannot be explicitly determined. In this case, the end points were deliberately selected to show how closely it is possible to approximate the profile with line segments.

Fig. 2 shows the temperature profile (dotted line) above the squall line. In this case the clouds were opaque and the temperature at the top of the cloud was found from the 899  $\text{cm}^{-1}$  results to be about 233° K. The solution in this case requires that the contributions by the cloud to the radiances be subtracted; that is, the contribution by the atmosphere alone must be determined. It is therefore a matter of successive approximations to determine the height of the cloud by having the solution coincide with the cloud temperature, which is already known. This process converges rapidly, inasmuch as there is already, even from climatology, a fair approximation to the height. Also in this solution we have determined the height of the tropopause from the trigonometric series solution, and then performed a line segment solution, spacing the other points so that the information content of the results was equally distributed according to the transmittance functions.

We conclude from our measurements that Kaplan's original suggestion is a practical proposition, and that

with satellite observations of comparable accuracy it should be possible to obtain meteorologically usable atmospheric temperature profiles. The U.S. Weather Bureau on the basis of these results has undertaken continued development of the instrument for a satellite experiment.

## GEOLOGY

### Age Determinations on Three African Carbonatites

CARBONATITES have been a normal part of the magmatic history of east, central and southern Africa over a long period of geological time. They range in age from those associated with Tertiary volcanoes of the Elgon group to the pre-Karoo carbonatites of Spitzkop and Loolekop in the north-eastern Transvaal. The salient features of most of the known African carbonatites have been summarized by Campbell Smith<sup>1</sup>.

Table 1. POTASSIUM-ARGON AGE DETERMINATIONS

Nature and location of sample	K (%)	Radiogenic <sup>40</sup> Ar	Age (m.yr.)
Mbeya	6.51	0.054 p.p.m.	113 ± 6
Kangankunde	7.59	0.069 p.p.m.	123 ± 6
Nkumbwa Hill	7.94	0.460 p.p.m.	680 ± 25

Decay constants:  $\lambda\beta = 4.72 \times 10^{-10} \text{ yr.}^{-1}$ ,  $\lambda\alpha = 0.584 \times 10^{-10} \text{ yr.}^{-1}$ .  
Isotopic abundance of <sup>40</sup>K = 0.0119 atom per cent.

Table 2. URANIUM-LEAD AGE DETERMINATIONS, MBEYA CARBONATITE

Sample	%U	%Th	%Pb	<sup>204</sup> Pb	<sup>206</sup> Pb	<sup>207</sup> Pb	<sup>208</sup> Pb	<sup>206</sup> Pb/ <sup>238</sup> U	<sup>207</sup> Pb/ <sup>235</sup> U	<sup>206</sup> Pb/ <sup>232</sup> Th

Pyrochlore, Chloritic Zone	0.311	0.71	0.090	1.27	26.47	20.17	52.09			

Decay constants: <sup>238</sup>U =  $1.569 \times 10^{-10} \text{ yr.}^{-1}$ ; <sup>235</sup>U =  $9.7216 \times 10^{-10} \text{ yr.}^{-1}$ ; <sup>232</sup>Th =  $4.8813 \times 10^{-11} \text{ yr.}^{-1}$ ; <sup>238</sup>U/<sup>235</sup>U = 137.7.

This communication gives the results of three K-Ar age determinations on micas from the carbonatites of Panda Hill (Mbeya, Tanganyika), Kangankunde (Chilwa Series, Nyasaland), and Nkumbwa Hill (Northern Rhodesia).

Mica concentrates were prepared using magnetic methods of separation so far as possible. Potassium was determined with an Eel flame photometer; argon was determined by isotope dilution using a 4½ in. radius, 60° Reynolds-type glass mass spectrometer. The argon was extracted by fusion of the mica sample in a glass vacuum system attached directly to the mass spectrometer. The calculated ages are believed to have an uncertainty of no more than ± 4 per cent (95 per cent confidence level).

*The Mbeya carbonatite.* Originally called the Panda Hill pyrochlore deposit, this carbonatite is 13 miles W.S.W. of Mbeya, near the south-west border of Tanganyika. It has been described in detail by Fawley and James<sup>2</sup>. The complex consists of a central plug and steeply inward-dipping outer ring of carbonatite and includes tuffs and agglomerates and an explosion-vent breccia; it also has a pyrochlore-rich zone with the form of an incomplete ring dyke. Much of the structure has been complicated by metasomatic and tectonic activity.

The carbonatite is overlain by Cretaceous sediments, and in the nearby Songwe River valley Karroo sediments are brecciated by minor explosive vents thought to be of the same age as the Panda Hill volcanicity. Thus, geo-

logical evidence indicated a Jurassic or Cretaceous age. The K-Ar age determination gives an age of 113 million years, which in terms of present estimates of the geological time scale corresponds to the Cenomanian stage at the base of the Upper Cretaceous (Table 1).

Age determinations have also been made by the uranium-lead method on two samples of pyrochlore from this carbonatite complex by Schurmann *et al.*<sup>3</sup>. The ages as calculated are discordant and range from 68 to 273 m.yr. However, it is impossible to tell from Schurmann's results whether the discordance reflects chemical alteration or is due to the use of the wrong isotope ratios when correcting for common lead contamination. Fortunately, since two samples have been analysed which can safely be assumed to be of the same age, and were in all probability contaminated by common lead having the same isotopic composition, it is possible to calculate ages independent of any assumptions regarding the isotopic composition of the common lead component. These ages are listed in Table 2 and are still discordant. Thus, it must be assumed that one or both of these pyrochlores have suffered chemical alteration and no other geological significance can be attached to these results.

*The Kangankunde carbonatite.* Kangankunde Hill, formed by an erosion-resistant carbonatite complex, is 50 miles west of Lake Chilwa in the Lower Shire area of southern Nyasaland. This ankeritic carbonatite complex is a member of the Chilwa Series (Dixey *et al.*<sup>4</sup>). The Chilwa Series comprises a group of vents, pipe-like in form, infilled by carbonatite and/or feldspathic breccia; syenite and nepheline-syenite intrusions; and a varied suite of minor intrusions, mainly in the form of dykes. The largest of these vents, namely, Muambe, intersects Karroo sediments and is in part overlain by the Lupata sediments and volcanics of Cretaceous age. The K-Ar age as determined on a phlogopite corresponds to the Albian stage of the Lower Cretaceous.

*The Nkumbwa Hill carbonatite.* This complex forms a hill of limestone rising more than 1,000 ft. above the

surrounding country in the Isoka district of Northern Rhodesia (Reeve and Deans<sup>5</sup>). The carbonatite cuts biotite-gneisses of unknown age. The K-Ar age determination on phlogopite from adjacent metasomatized country rocks indicates a late Precambrian time of emplacement.

*Conclusions.* Age determinations on the Mbeya and Kangankunde carbonatites give results indicating emplacement during the Cretaceous. Such geological evidence as is available indicates an Upper Jurassic or Lower Cretaceous age. Bearing in mind the experimental errors and the possibility that one or both of the analysed micas may have suffered slight argon loss, it is reasonable to suggest that these complexes are actually of the same age. In contrast, the Nkumbwa Hill carbonatite is much older.

## CHEMISTRY

## Phototropic Enzyme-dye Complexes

THE term 'phototropy' has been applied to the phenomenon of a reversible change of colour induced by coloured lights, as in fulgides, and the change in or loss of colour of dye-stuffs in light of specific wave-length. The term has been used by chemists, botanists, biologists, and biochemists for many years to explain this phenomenon of change in colour of solids and solutions. Several reviews on the subject have been published<sup>1-6</sup>. A number of investigators have attempted to interpret the cause of phototropy in solutions<sup>7,8</sup>. The dyes most commonly used to explain the mechanism of this phenomenon have been the leucocyanides. The phototropy of malachite green leucocyanide has been investigated in dry alcohol and also in mixtures of alcohol and water by a number of authors<sup>9-15</sup>.

The phototropic triphenylmethane dyes are capable of reactions with quantum yields approaching unity in some solvents. Very high extinction coefficients and broad spectral coverage are characteristic properties. However, these dyes exhibit slow reversal time from coloured to colourless state and fatigue during cyclic exposure.

An investigation was conducted to determine the effect of enzymes on the phototropic behaviour of triphenylmethane dyes. It was found that triphenylmethane dyes and certain enzymes form phototropic systems which demonstrate unique properties in changing from a colourless to a highly coloured state under the influence of ultra-violet light. The unique properties demonstrated by this system are resistance to cyclic

Fig. 1

Fig. 2

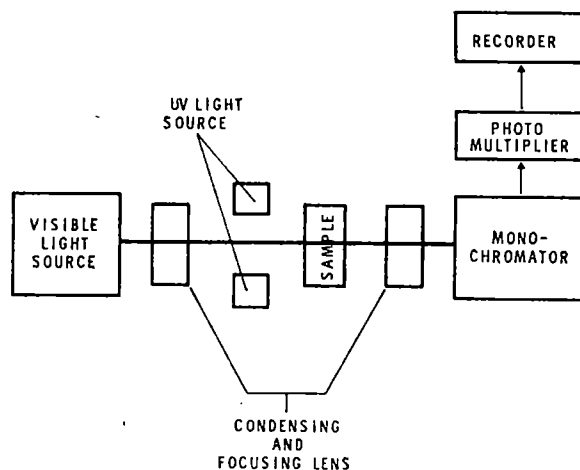

Fig. 3. Flash photolysis unit

Fig. 4

fatigue, ultra-fast reaction to ultra-violet light stimulus, and reversibility of colour when the source of light is removed. This system is effective as a filter for high-intensity, ultra-violet activated light sources.

Solutions of rosaniline red and malachite green were prepared as follows (in g): dye, 0.02; papain, 0.20;  $\text{NaHSO}_3$ , 0.40; water, 100.

Rosaniline red shows a 100 Å shift (from 5400 Å to 5500 Å) in peak absorption when combined with papain, when measured on a Cary model 14 spectrophotometer, indicating the possible formation of a complex (Fig. 1). Malachite green-papain solutions exhibit a peak intensity at 6180 Å, but little perceptible shift.

To determine the effect of papain on cyclic fatigue resistance, solutions of malachite green with and without papain were exposed to steady-state illumination of a 275-W ultra-violet lamp for 10 sec periodically, with optical densities measured before and after each exposure in a Bausch and Lomb photometer. Fig. 2 shows that the malachite green-papain solution resists cyclic fatigue after 50 cycles whereas malachite green alone shows a steady deterioration in the ability to resist cyclic fatigue.

Response time to achieve maximum optical density of the malachite green-papain solution was measured on a special flash photolysis unit (constructed by the National Cash Register Company, Dayton, Ohio; Fig. 3). The 200-W-sec ultra-violet flash source attains peak intensity in 25  $\mu\text{sec}$ , with a 50 per cent fall-off from peak intensity in 65  $\mu\text{sec}$  from zero time. Maximum optical density of the malachite green-papain solution was attained in 25  $\mu\text{sec}$ . This response time is independent of either the dye or enzyme concentration. However, the degree of optical density is dependent on light intensity and dye concentration.

Reverse reaction rates (that is, colour decay) were found to be influenced by the pH of the solution, bisulphite concentration and the presence of papain. Another experiment conducted with a malachite green-papain solution at a pH of 7.1 showed definite increase of colour decay rate in the presence of papain as shown in Fig. 4.

It is postulated that an enzyme-dye complex is formed as a first step and one or more additional steps would take place on irradiation until the dye cations were produced, as represented as follows:

The presence of radiant energy in the process may, of course, alter the role of the enzyme as a catalyst, although it should be noted that peak absorption wave-length of papain lies in the ultra-violet range which is beyond the 3000 Å–4000 Å peaks intensity of the light source used in the work recorded here. If the enzyme were acting in some capacity other than as a catalyst, it might be retaining the cation and anion after photo-disassociation in close proximity to each other, thus acting as a cage. Needless to say, these postulations are greatly simplified and may not represent the true mechanism of the process.

## A New Physical Constant for Solutes

A RELATIONSHIP was established earlier between the dispersion ratio (a measure of the property of gradation of density of the solute in a frozen and thawed column of solution) and the specific gravity of the solute<sup>1</sup>. At the same time it was found that there was no correlation between the dispersion ratio and the molecular weight of the solute, and attention was directed to the significance of this.

Further investigations have now revealed a neat relationship between the mole fraction of the solute and its dispersion ratio. The relevant data obtained in the experiment on a mixture of solutes given in the table in the last communication<sup>1</sup>, plotted on this basis, are shown in the curve in Fig. 1 (a).

The relationship, further, becomes practically linear when the two factors are correlated, as in the graph in Fig. 1 (b), in terms of their logarithms.

This finding has been confirmed by an experiment on the same single solute. Potassium permanganate solutions, in a rising series of initial concentrations, were frozen and thawed in 250 ml. cylinders, and the dispersion ratio determined as before. The direct variation of the logarithm of the dispersion ratio with that of the mole fraction of the solute in the series is brought out in Fig. 2.

Fig. 1. A,  $K_2SO_4$ ; B,  $Al_2(SO_4)_3$ ; C,  $CuSO_4$ ; D,  $FeSO_4$ .

Fig. 2

The rise of the dispersion ratio with the initial concentration of the solute, for the series of concentrations tried in the experiment, fits into the simple equation:

$$Y = Mx$$

where  $Y$  is the logarithm of dispersion ratio;  $x$ , the logarithm of mole fraction of solute;  $M$ , the constant of proportionality.

For potassium permanganate, the constant of proportionality, which may be termed the 'cryoscopic effect constant' (as distinct from the cryoscopic constant<sup>2</sup>), was found to be about 0.71 in this experiment. With the standardization and refinement of the method of determination of the dispersion ratio, the value of the constant will become more exact.

These findings lead to the inference that the 'cryoscopic effect constant', like the dispersion ratio, can be expected to be characteristic of the solute. A comparative investigation of the constant for various categories of solutes and for various solvents, as well as their correlation with other constants of the solute, will perhaps throw more light on the properties of matter.

I wish to thank Mrs. Parvathy Rangappa and Mr. R. N. Sood for assistance in these experiments.

### Ferrocene-containing Polymers: Intermediary Complex Formation in the Polycondensation of *N,N*-Dimethylaminomethylferrocene

In an earlier paper<sup>1</sup> discussing the  $\text{ZnCl}_2$ -HCl-catalysed polycondensation of *N,N*-dimethylaminomethylferrocene I to give polymer II, the formation of intermediates III and IV was postulated on the basis of the stoichiometry of the starting materials required and the composition of by-product V ( $\text{C}_{10}\text{H}_9\text{Fe}$  = ferrocenyl). While III could indeed be isolated, no interception of IV was possible.

(II)

The isolation of IV has now been accomplished from polycondensation reactions interrupted prior to completion. For example, from experiments (20–40 min, 160°) conducted by the conventional procedure<sup>1</sup>, using I,  $\text{ZnCl}_2$  and HCl in a 2 : 1 : 2 ratio, IV was separated in 5–9 per cent yield besides III and V by fractional crystallization from the isopropanol extract of the reaction mixture. Similarly, equimolar amounts of I,  $\text{ZnCl}_2$  and  $\text{H}_2\text{O}$  (HCl generated by hydrolysis) at 160° (4 h) gave IV in 8.7 per cent yield. The water-soluble complex forms yellow plates, m.p. 140°–142° (calc.: C, 36.22; H, 5.27; Cl, 28.51; Fe, 11.23; N, 5.63; found: C, 36.56; H, 5.35; Cl, 28.31; Fe, 11.52; N, 5.94); in aqueous or alcoholic solution it dissociates (further dissociation of the tetrachlorozincate ion in the equilibrium  $\text{ZnCl}_4^{2-} \rightleftharpoons \text{Zn}^{2+} + 4\text{Cl}^-$  may be neglected here) according to equation I, as indicated by chemical reactions and molecular weight determinations<sup>1</sup>.

The 3.30  $\mu$  band ( $\text{CH}_3$  on  $\text{N}^+$ ) in the infra-red spectrum (potassium bromide pellet) of IV was almost as strong as in V, whereas the stretching band near 2.85  $\mu$ , strong in III, showed considerable attenuation. Decreased intensity was

also observed with the  $\text{NH}_2^+$  bands near 4.2, 6.4 and 11.35  $\mu$  (stretching, bending, rocking). No  $\text{NH}^+$  absorption in the 3.8–4.1  $\mu$  region (as exhibited by the hydrochloride of I) was noticed. These findings suggest protonation of the dimethylamine nitrogen, while the Mannich base nitrogen appears to exist essentially in a non-protonated form as analogously suggested<sup>1</sup> for III, and, hence, may involve co-ordinate covalent  $\text{N} \rightarrow \text{Zn}$  bonding.

VIa,  $R = \text{H}$

VIb,  $R =$  residual polymer chain

The isolation of IV in addition to III during intermediate stages of the polycondensation of I corroborates the reaction course proposed earlier. (IV was also directly obtained by fusing a 1 : 1 mixture of III and V. This reaction, well in accord with the evidenced double-salt character of the compound, is expected and not contradictory to the reaction path postulated.) The primary complex III is formed from I,  $\text{ZnCl}_2$  and HCl (equation (3a), *loc. cit.*<sup>1</sup>). Aided by  $\text{N} \rightarrow \text{Zn}$  co-ordination, III dissociates at one of the two  $\text{C}_a-\text{N}$  bonds, and the resulting IV undergoes further ionization at the remaining  $\text{C}_a-\text{N}$  bond, thus leading to V. The metallocarbocations VIa produced in these two ionization steps (and, similarly, VIb arising from polymeric analogues of III and IV in advanced stages of propagation) may now undergo the earlier proposed propagation and termination steps leading to II.

### Stereochemistry of Copper in *Bis*(*N*-*t*-butylsalicylaldiminato)copper(II)

It has been established that copper(II) will adopt an approximately tetrahedral environment under certain circumstances but evidence on the exact geometry of this configuration is still meagre. That which is available, with two possible exceptions<sup>1,2</sup>, shows a stereochemistry which is more nearly planar than tetrahedral<sup>3</sup>. For instance, in 2,2'-biphenylbis-(2-iminomethylenephenoate) copper(II), where copper is complexed by a tetradentate molecule with donor atoms which are naturally tetrahedrally disposed, the ligand is considerably distorted and the expected 90° angle between the two planes containing the salicylaldimine groups is reduced to 43°.

A recent investigation of *bis*(*N*-isopropylsalicylaldiminato)copper(II) (ref. 1) has shown the crystals to be nearly, but not perfectly, isomorphous with those of the analogous nickel complex, which in its turn has been shown by X-ray analysis<sup>4</sup> to adopt a configuration which is only slightly distorted from tetrahedral. The angle between the salicylaldimine planes is 81° and the six bond angles about the nickel atom range from 94° to 125°. It is deduced that the copper atom has a similar configuration. Steric arguments, together with spectral data and dipole moment

evidence<sup>1</sup>, suggest that *bis*(*N*-*t*-butylsalicylaldiminato) copper(II) is even more likely to be tetrahedral, and in order to provide some precise information we have made a three-dimensional X-ray analysis of this compound.

The crystals are orthorhombic with  $a = 9.11$ ,  $b = 11.17$ ,  $c = 21.35$  Å and the space group is  $P2_12_12_1$ . The copper atoms were located from the Patterson syntheses  $P_{uu}$  and  $P_{vv}$ , and a three-dimensional heavy-atom electron-density synthesis, computed with weighted coefficients<sup>2</sup>, then showed all the light atom positions. The distinction between carbon, nitrogen and oxygen was made on chemical grounds. One 'difference' cycle, to confirm the co-ordinates, and three least squares refinement cycles have reduced the reliability index to 0.099 for the 2,209 observed reflexions. Separate isotropic temperature factors were applied to all atoms.

Fig. 1

The atomic arrangement in the molecule is shown in Fig. 1. Most bond lengths and angles are normal but the stereochemistry about the copper atom is far from regular. The angle between the mean planes containing the salicylaldimine residues is  $80^\circ$ , suggesting a basically tetrahedral environment, but the bond angles about the copper atom show this to be more flattened than in the above nickel compound. The most striking feature is the distortion of one of the salicylaldimine groups, but not the other, from co-planarity with the copper atom. In one-half of the molecule the plane of the benzene ring contains, within small deviations, all atoms of the chelate ring, including the copper. In the other half the deviations from the plane defined by the benzene ring are, for the atoms copper, nitrogen, aldehyde carbon and oxygen,  $+0.67$ ,  $-0.01$ ,  $-0.12$  and  $+0.04$  Å respectively. The tertiary carbon atom of the *t*-butyl group is  $-0.27$  Å from this plane. (The sense of the signs is apparent from Fig. 1.)

There is no obvious explanation for this quite unusual distortion. The chelate group has been twisted away from the position it would naturally occupy if the stereochemistry were flattened tetrahedral but not in any way so as to restore some planarity to the co-ordination arrangement. Space models built with planar salicylaldimine groups and with the measured bond angles about the copper atom show satisfactory approach distances to the neighbouring *t*-butyl group and give no indication of intramolecular steric strain. There are no intermolecular

contacts of less than  $3.6$  Å in the observed structure but the packing of the molecules is indeed compact and it may be that with unwieldy molecules, such as these, crystal packing forces have more influence on the shape of the molecule than might otherwise be supposed. On the other hand, it is possible that the copper atom itself induces the deformation. Certainly the observation that the dipole moment of this compound in benzene solution is only two-thirds that of its cobalt(II) analogue<sup>1</sup> suggests it has some structural influence.

## New Types of Aromaticity

RECENTLY it has been shown<sup>1</sup> that the two ideas of aromatic character and the aromatic sextet, which are generally associated in current theory, are not necessarily connected and that in addition to the well-known  $p_\pi-p_\pi$  bonding of the cyclic polyenes and aromatic hydrocarbons there is a second type,  $d_\pi-p_\pi$  bonding, which is exemplified notably by the phosphonitrilic halides. The two types have been termed<sup>2</sup> 'homomorphic' and 'heteromorphic', respectively, and it has been demonstrated<sup>1,2</sup> that, in terms of the site-symmetry of the atomic orbitals combined to form molecular  $\pi$ -orbitals, there are only these two forms of cyclic  $\pi$ -bonding.

Each of the two forms may be subdivided into two topological classes, however, giving four types of cyclic  $\pi$ -bonding which are distinguished by a particular relationship between the total  $\pi$ -electron energy and the number of conjugated atoms of the cyclic system. The first of the four types to be identified was that of the Hückel cyclic polyenes<sup>3</sup>. In the approximation where each of the  $n$  conjugated carbon atoms has the same coulomb integral  $\alpha$ , and each of the carbon-carbon bonds the same resonance integral  $\beta$ , the energies of the molecular orbitals are:

$$E_j = \alpha + 2\beta \cos(2\pi j/n) \quad (1)$$

where the quantum number  $j = 0, \pm 1, \pm 2 \dots (n/2)$ . The Hückel cyclic polyenes have a closed-shell ground-state configuration if  $n/2$  is odd and a total  $\pi$ -electron energy given by:

$$E_\pi = n\alpha + 4\beta \operatorname{cosec}(\pi/n) \quad (2)$$

whereas the rings with  $n/2$  even have an open-shell ground-state configuration and a total  $\pi$ -electron energy of:

$$E_\pi = n\alpha + 4\beta \cotan(\pi/n) \quad (3)$$

The second type of cyclic  $\pi$ -bonding, exemplified by the phosphonitrilic halides, consists<sup>1,2</sup> of alternating  $p_\pi$  and  $d_\pi$  orbitals, the latter being tangential to the ring. The resonance integrals  $\beta$  of the  $\pi$ -bonds have the same magnitude, but those of adjacent bonds now have opposed signs in the basis model exhibiting the cyclic equivalence of each of the two kinds of atomic orbital. If it is assumed for the purpose of illustration that all of the  $n$  conjugated atoms have the same coulomb integral  $\alpha$  the energies of the molecular  $\pi$ -orbitals are:

$$E_j = \alpha \pm 2\beta \sin(2\pi j/n) \quad (4)$$

where the quantum number  $j = 0, \pm 1, \pm 2 \dots (n/4)$  or  $(n-2)/4$  for the cases of  $n/2$  even or odd, respectively. In

this approximation the rings with  $n/2$  either odd or even have an open-shell configuration in the ground state and the lower  $\pi$ -energy per electron given by equation (3). The introduction of different coulomb integrals for the two sets of atoms, the nitrogen and phosphorus atoms of the phosphonitrilic halides, gives the system a closed-shell ground state, but it does not affect the conclusion<sup>1,2</sup> that the  $\pi$ -energy per electron is a smooth function of  $n$  and not an oscillatory function, depending on the even or odd character of  $n/2$ , as in the case of the Hückel cyclic polyenes.

The formalism of the third type of cyclic  $\pi$ -bonding may be derived<sup>4</sup> from a model constructed schematically by cutting any one bond of a Hückel cyclic polyene and rejoining the ends after twisting them mutually by  $180^\circ$  so that the  $\pi$ -electron system consists of a Möbius strip of conjugated  $p_\pi$  orbitals. The resonance integrals  $\beta$  of the Möbius cyclic polyenes have the same magnitude, but one of them is of opposite sign to the others, and for such a system with  $n$  conjugated atoms, each having the same coulomb integral  $\alpha$ , the energies of the molecular  $\pi$ -orbitals are:

$$E_j = \alpha + 2\beta \cos(\pi j/n) \quad (5)$$

where the quantum number  $j = \pm 1, \pm 3, \pm 5, \pm 7 \dots \pm (n-1)$ . The Möbius cyclic polyenes are anti-Hückel<sup>4</sup> in that those with  $n/2$  odd have ground states with open-shell configurations and the lower  $\pi$ -energy per electron given by equation (3), whereas the Möbius rings in which  $n/2$  is even have closed-shell ground-state configurations and the higher  $\pi$ -energy per electron given by equation (2).

The Möbius ring formalism applies to any cyclic  $\pi$ -bonded system in which one or an odd number of  $\pi$ -bond resonance integrals have the same magnitude but an opposite sign to the others, for example a Hückel cyclic polyene in which one  $p_\pi$  orbital has been removed and replaced by a tangential  $d_\pi$  orbital. The phosphorus analogue (I) of benzene, recently prepared<sup>5</sup>, is of this type. The molecule (I) has a closed-shell ground-state configuration, owing to the different coulomb integrals of phosphorus and carbon atoms, and it is probable that the resonance integrals  $\beta_{PC}$  and  $\beta_{CC}$  have different magnitudes, but the general formalism of the Möbius rings suggests that the corresponding phosphorus analogues of cyclobutadiene and cyclo-octatetraene, as yet unknown, would have a larger  $\pi$ -energy per electron than (I).

The fourth type of cyclic  $\pi$ -electron system consists of a Möbius strip of alternating  $p_\pi$  and tangential  $d_\pi$  atomic orbitals or, what is formally equivalent, a ring of the second type in which one of the  $d_\pi$  orbitals has been replaced by a  $p_\pi$  atomic orbital, or one of the  $p_\pi$  by a  $d_\pi$  orbital. If all of the  $n$  atoms of the ring have the same coulomb integral  $\alpha$  and all of the  $\pi$ -bonds a resonance integral  $\beta$  with the same magnitude the energies of the molecular  $\pi$ -orbitals are:

$$E_j = \alpha \pm 2\beta \sin(\pi j/n) \quad (6)$$

where the quantum number  $j = 1, 3, 5, 7 \dots (n-1)$ . Rings of the fourth type with  $n/2$  either even or odd have a closed-shell ground-state configuration and the higher  $\pi$ -energy per electron given by equation (2). Another recently prepared<sup>5</sup> phosphorus analogue (II) of benzene

exemplifies the fourth type of cyclic  $\pi$ -bonded system, although in any detailed treatment of molecule (II) it would be necessary to take account of the different magnitudes of  $\alpha_P$  and  $\alpha_C$  and of  $\beta_{PC}$  and  $\beta_{CC}$ .

The cyclic  $\pi$ -bonded systems of the first and the third types are fundamental topologically in that their characteristics derive, respectively, from the even or the odd number of resonance integrals with a given sign in the ring. Thus in the second type of ring system there is an even number of resonance integrals with the same sign if  $n/2$  is even (type 1 behaviour), but an odd number if  $n/2$  is odd (type 3 behaviour), so that all rings of the second type have the smaller  $\pi$ -energy per electron (equation (3)) and an open-shell ground-state configuration in the approximation where it is assumed that the coulomb integrals of the two sets of atoms are equal. Conversely, for the fourth type of ring system there is an odd number of resonance integrals with a given sign if  $n/2$  is even (type 3 behaviour) and an even number if  $n/2$  is odd (type 1 behaviour), giving all rings of the fourth type the larger  $\pi$ -energy per electron—(equation (2)).

## BIOPHYSICS

### A Resemblance between the Clotting of Blood Plasma and the Breakdown of Cytoplasm

THE urge to regard vertebrate blood plasma as a descendant of protozoan cytoplasm is an old one. It is supported by discovery of various similarities between the clotting of plasma when shed, and that of cytoplasm when extruded. Both need calcium ions, yield similar (thromboplastin) enzymes, are accelerated by thrombin and in some cases inhibited by heparin<sup>1</sup>.

Some physical changes occurring in the cytoplasm of damaged cells appear transient. They were investigated by Kopac<sup>2</sup> with a technique based on the principle that an oil drop introduced into a cell will adsorb a protein film at the oil/cytoplasm interface; if afterwards one reduces the interfacial area, one will compress such a film until visible wrinkling (Devaux effect) occurs. This wrinkling is provoked by a minimum of compression or even spontaneously if the oil drop had been introduced shortly after the cell had been damaged by other means. Apparently, at that time cytoplasmic lipophilic proteins become available which are in part adsorbed at the oil interface where they expand (perhaps by becoming more helical); those left unadsorbed will become restabilized by mutual attachment at available apolar groups, since, in an aqueous medium, exposure of hydrophobic amino-acid groups will be unstable<sup>3</sup>. The newly formed protein/protein complexes may be of such strength that an apolar interface introduced at this time can no longer compete for their masked apolar sites; hence no spontaneous Devaux effect can be provoked from then on.

During the clotting of mammalian blood, similar interactions may take place among various proteins. These may be arranged (Fig. 1) according to the availability of their apolar sites, as judged by wettability<sup>4</sup>, activity<sup>5,6</sup> and optical thickness<sup>7</sup> of films adsorbed at hydrophilic and hydrophobic interfaces. Factors XI, V, VIII, thrombin and fibrinogen are preferentially adsorbed

Fig. 1. Diagram of coagulation reactions. Outline around factors IX, X and prothrombin is intended to suggest that these factors may be part of one molecule. Presumed degree of effective apolarity among factors shown as increasing toward the right. ++ indicates reaction demands calcium ions

on to hydrophobic surfaces such as barium stearate and aluminium octoate powders; experimental and other evidence was reported in detail elsewhere<sup>8</sup>. *In vivo*, and before surface activation, those clotting factors with apolar sites most available may circulate as dimers, or as complexes with each other and with lipids. From the chain of clotting reactions proposed by most current theories (arrows, Fig. 1), the following can be selected to suggest involvement of hydrophobic bonds. At the onset of clotting, factor XII is electrostatically adsorbed on to a surface (such as glass), so that its more apolar sites become exposed to the medium and will in turn adsorb factor XI by hydrophobic bonding. Factor XI, changed in shape with its hydrophobic bonds now fixed by those of factor XII, activates factor IX in an electrostatic interaction which demands a bridge of calcium ions. Hydrophobic sites in factor IX then become attached to those readily available in factor VIII, and allow interaction of factor VIII with polar factor X. The resulting complex absorbs a negatively charged phospholipid micelle and opens it to expose its apolar fatty acid tails which can now adsorb and activate factor V, a protein we presume to be rich in available hydrophobic bonds. The final product enzymatically disrupts prothrombin molecules, exposing the hydrophobic bonds of thrombin which in turn will serve as point of attachment to similar bonds in fibrinogen, thus aligning enzyme and substrate. It is equally possible that factors IX, X and thrombin are parts of one molecule<sup>4</sup> (prothrombin) which demands disruption of increasing numbers of hydrophobic bonds, and thus increasingly hydrophobic enzymes, as its thrombin core is reached (Fig. 1). After coagulation, the activity of most 'apolar' factors disappears, or their apolar sites become permanently unavailable.

Both coagulation of mammalian blood plasma, and the breakdown of cytoplasm in damaged cells, may therefore involve the passage of transient hydrophobic bond

exposure from protein to protein, and techniques so far used for the examination of the one phenomenon may be applied to the other.

## BIOCHEMISTRY

### Cross-over Electrophoresis of Acid Mucopolysaccharides

WE wish to direct attention to a simple modification of an electrophoretic technique for acid mucopolysaccharides (AMP) which makes definition of zones clear. The equipment used is the Beckman 'Microzone' electrophoresis unit which permits the placing of constant volume samples (0.25  $\mu$ l.) on buffer soaked strips of cellulose acetate.

In the commonly used method the separation proceeds with a constant voltage of 250 V and an initial 3 m.amp for approximately 25 min with either a pH 8.6 veronal or pH 2.5 acetic acid buffer. After the separation the strip is dried and spray-stained for AMP with toluidine blue, alcian blue or acridine orange solution<sup>1,2</sup>.

In the proposed modification the dye is deposited in a continuous line at the positive end of the electrophoretic strip 5 min after the current is turned on. A narrow strip of blotting paper saturated with concentrated dye in the electrophoresis buffer gives the best results. The dye migrates toward the AMP and when the dye and AMP fronts meet they co-precipitate. The slower, or diffused, part of each zone of AMP is allowed to catch up and precipitate at the front of each zone. The dye, present in excess, crosses the zone of precipitation and migrates toward the next zone of polysaccharide. The run is continued until the dye migrates past the AMP origin. Unreacted dye is rinsed away with distilled water. The dye most suited to this process, 'cross-over electrophoresis', is acridine orange. It should be recrystallized from concentrated ethanol solution in the presence of the buffer salts used in the electrophoresis and should be stored in light-proof containers<sup>3</sup>. The ionic strength of the buffer should be no higher than 0.10 because the dye complex with non-sulphated AMP dissociates above this ionic strength.

Fig. 1

A buffer made by mixing 4 volumes of formic acid with one volume of sodium acetate, each at 0.10 M, gives a pH of 2.0. This seems most useful for separating AMP of different degrees of sulphation. With veronal buffer at pH 8.6 the technique can be used for the separation of non-sulphated glycoproteins and AMP.

The AMP present in a 1 cm square 10 $\mu$  section of cartilage are easily detected and separated. As little as 0.05  $\mu$ g of standard AMP is easily detected and 0.3  $\mu$ g can be measured by scanning cleared strips in the Beckman 'Microzone Analytrol'.

Fig. 1 illustrates the separation of hyaluronic acid (HA), chondroitin sulphuric acid (CSA) and heparin from a mixture of standards. The scan is made directly from the cleared strip which was also used as the 'negative' for the enlarged print of the separated zones.

### Enzymatic Action of Lipoglycoprotein Preparations from Sperm-acrosomes on Rabbit Ova

THE cumulus oophorus of rabbit eggs can be dispersed *in vitro* by suspensions of rabbit spermatozoa<sup>1,2</sup> or by hyaluronidase<sup>3</sup>, but the corona radiata remains intact<sup>4</sup>. Both the corona and the zona pellucida can be dissolved by proteolytic enzymes such as ficin, papain, 'Pronase' (a bacterial proteinase) and trypsin<sup>5,6</sup>, but the mechanism by which dissolution is brought about *in vivo* remains obscure<sup>6</sup>. However, it is known that when spermatozoa penetrate the layers of cumulus and corona cells of rabbit eggs the acrosomes become detached<sup>6</sup>, and it has been suggested that this leads to liberation of a 'zona lysin', a hypothetical enzyme which is localized between the sperm head and the acrosome<sup>7</sup>.

Acrosomes can be dislodged from ram, bull and rabbit spermatozoa by means of anionic detergents and obtained as suspensions which are almost free from any other parts of the sperm cell<sup>8,9</sup>. The separated acrosomes become solubilized, in the form of a lipoglycoprotein complex, following treatment with ethanol<sup>9</sup>.

When freshly ovulated rabbit eggs were incubated at pH 7 and 37° C with lipoglycoprotein complex from ram, bull or rabbit spermatozoa the eggs became denuded, that is, cumulus and corona cells were dispersed. In some cases dissolution of the zona pellucida was also observed. When the eggs were stationary in the lipoglycoprotein solution, up to 24 h was necessary for full effects to be observed, but with occasional gentle shaking the process of denudation occurred more rapidly. Control experiments without lipoglycoprotein complex showed no denudation. The denuding activity of lipoglycoprotein complex was much lower after it had been heated to 100° C. Activity was also decreased by iodoacetate and by the polyanionic hyaluronidase inhibitor 53DK<sup>10</sup>, although with both inhibitors the extent of inhibition varied widely from one preparation to another. The lipoglycoprotein complex preparations contained some hyaluronidase; but there was no parallelism between denuding activities and hyaluronidase contents. The preparations also showed proteolytic activity, reflected in the liberation of amino groups, when incubated alone at pH ~7. In presence of

air this proteolytic activity was low (0.2–0.6  $\mu$ equiv. amino-acids/h/mg lipoglycoprotein complex) but rates in absence of oxygen were 2–3 times greater.

The experiments briefly reported here provide the first demonstrations of a denuding effect on ova, and a dissolution of the zona pellucida, by a cell-free enzyme preparation with proteolytic activity, obtained from mammalian spermatozoa.

### Relationship between Concentrations of Ruminal Nucleic Acids and Excretion of Purine Derivatives by Sheep

PURINES can be synthesized in the animal body from glycine, serine, aspartic acid, glutamine, formate and respiratory carbon dioxide, but they are also derived from dietary and cellular nucleoprotein. Recent work with cattle<sup>1</sup> and sheep<sup>2</sup> has shown that purine derivatives (uric acid and allantoin in urine) are quantitatively important end-products of these ruminants when they are fed on diets with a high-energy, low-protein content and when the animals are in either N equilibrium or slight positive balance. With such diets protein is utilized very efficiently. It is well known that efficiency of protein utilization in the ruminant depends on the catabolic and synthetic activities of the rumen micro-organisms. For high efficiency, the breakdown products of dietary protein and other nitrogenous compounds must be rapidly synthesized into microbial protein in the rumen<sup>3</sup>. This evidence suggests that most of the allantoin and uric acid excreted by ruminants may be derived from nucleic acids of rumen micro-organisms. Some support for this suggestion has been reported by Blaxter and Martin<sup>4</sup>, who showed that after ruminal infusion of casein (which is free of purine and pyrimidine bases) slightly more allantoin was excreted than after abomasal infusion of the same quantity of casein.

In trials briefly described in this communication, the relationship was examined between ruminal concentrations of nucleic acids and the urinary excretion of allantoin and uric acid by sheep which were fitted with rumen cannulae and fed on a variety of low-protein diets.

Sixteen diets, ranging in crude protein content from approximately 2.6 to 10 per cent and varying in digestible energy content (four levels) were offered *ad lib.* to four groups of four fistulated wether sheep for periods of 28 days (the detailed composition of the diets and the experimental plan have been described previously<sup>5</sup>). In the last week of each 28-day period the sheep were housed in metabolism crates and total urinary collections were made. Samples of rumen fluid, approximately 50 ml. in volume, were taken at 7 a.m., 8 a.m., 9 a.m., 11 a.m. and 4 p.m. during one day of this collection period. The 7 a.m. and 4 p.m. samples were withdrawn immediately before feeding at these times. The rumen fluid was

aspirated from a constant depth (6 in.) into a  $\frac{3}{8}$ -in.-diameter glass tube and strained through four layers of muslin to remove coarse food particles. Four ml. of strained fluid were mixed with 10 ml. of 10 per cent (w/v) trichloroacetic acid, and centrifuged. The precipitate was extracted with 10 per cent trichloroacetic acid, ethanol and a mixture of ethanol and ether, and then hydrolysed using the method of Schneider<sup>6</sup>. The hydrolysed extract was diluted to 50 ml. with 5 per cent (w/v) trichloroacetic acid and its absorption of ultra-violet light measured on a Unicam spectrophotometer SP500 at 263 m $\mu$ . Compensation for absorption of ultra-violet light by the solvent was made by measuring the extracts against a blank of 5 per cent trichloroacetic acid. In the absence of a more suitable standard, yeast nucleic acid (supplied by B.D.H.) was hydrolysed by the same procedure and was used as a reference material. It was found that the maximum absorption of hydrolysates of ruminal extracts varied between 260 and 268 m $\mu$  but all measurements were made at 263 m $\mu$ . Allantoin content of the urine samples was determined by the method of Young and Conway<sup>7</sup>, and uric acid by the procedure of Benedict and Franke<sup>8</sup>.

Table 1. MEAN VALUES FOR URINARY LOSS OF URIC ACID PLUS ALLANTOIN, AND CONCENTRATIONS OF RUMINAL NUCLEIC ACIDS, FOR GROUPS OF FOUR SHEEP GIVEN FOUR DIFFERENT TYPES OF DIET

Diet	Urinary loss of uric acid plus allantoin nitrogen (mg/24 h)	Concentration of nucleic acid in rumen fluid ( $\mu$ g/ml.)
High energy	544 $\pm$ 260	187 $\pm$ 139
High roughage	312 $\pm$ 93	76 $\pm$ 39
All roughage	307 $\pm$ 120	91 $\pm$ 35
Dried veldt grass	236 $\pm$ 109	78 $\pm$ 50

The 16 different diets used in the trial comprised four high-energy diets (equal parts of concentrate and roughage), four high-roughage diets (6 parts of roughage with 1 part of concentrate), four diets composed entirely of roughage and four diets of dried veldt grass. Mean values of ruminal nucleic acid levels and uric acid plus allantoin excretion by sheep fed on the four groups of diets are shown in Table 1. Both the excretion of purine derivatives by sheep and the level of nucleic acids in the rumen were highest when they were given the high-energy diets. These diets, which were rich in readily fermentable carbohydrate, would encourage multiplication of micro-organisms in the rumen, which in turn would tend to cause high levels of ruminal nucleic acids. This association between nucleic acids and amount of synthesis in the rumen is supported by the observation that the concentration of nucleic acids in the rumen liquor during the day was generally highest in the 4 p.m. sample, that is, in 46 of the 64 samplings, while second highest concentration occurred most frequently at 7 a.m. During the time between feeding and these observed peaks there is probably a steady increase in the amount of microbial protein synthesized from the food ingested.

Fig. 1. Relationship between concentration of ruminal nucleic acids and excretion of purine derivatives by sheep

In Fig. 1 the mean daily excretion of nitrogen, in the form of uric acid plus allantoin, by the 16 sheep each given four different diets, is plotted against the weighted mean concentration of nucleic acid in the sheep's rumen during a day when the sheep was given the particular diet (a total of 64 observations). The weighted mean concentrations of nucleic acids were obtained by assuming linear changes between consecutive observations during the day. There was a highly significant correlation between the concentration of ruminal nucleic acids and the amount of uric acid plus allantoin nitrogen excreted ( $r = 0.537$ ;  $P < 0.001$ ).

Unfortunately there is, as yet, no convenient method of assessing the total daily production of substances in the rumen. The concentration observed at any time is dependent on the rate of synthesis of the substance and its rate of disappearance from the rumen. The latter is controlled by the rates of absorption, decomposition, and propulsion along the digestive tract. However, studies with metabolites such as volatile fatty acids<sup>9</sup> have shown that there is a close relationship between their concentration in the rumen and their rate of production. The highly significant correlation obtained in the trial now described, between ruminal concentrations of nucleic acids and the amount of purine derivatives excreted in urine by sheep, strongly indicates that nucleic acids produced in the rumen are the main source of purines from which uric acid and allantoin are derived by partial oxidation. It is possible that a more precise correlation would have been obtained between levels of uric acid plus allantoin excreted and ruminal nucleic acids had it been feasible to measure the daily rate of production of the latter with sufficient accuracy.

If ruminal nucleic acids are the main source of allantoin and uric acid found in the urine of ruminants, this does explain why the percentage of urinary nitrogen present as allantoin was found to be a useful index of efficiency of protein utilization<sup>1</sup>. For similar reasons, levels of nucleic acids in the rumen may be another useful characteristic for assessing the efficiency of protein utilization by ruminants.

### Histochemical Localization of $\beta$ -Glucuronidase in the Rat Brain

THERE are earlier reports of the biochemical demonstration of  $\beta$ -glucuronidase in brain tissue<sup>1,2</sup>. Strong  $\beta$ -glucuronidase activity in the choroid plexus and in the Purkinje cells was established by Pearse<sup>3</sup>. We have, however, been unable to find a more detailed investigation of the distribution of this enzyme in the brain.

Our histochemical investigations showed that  $\beta$ -glucuronidase activity is widely distributed in the rat brain. A pronounced and precisely localized reaction was found

Fig. 1.  $\beta$ -Glucuronidase activity in the brain of the rat. Fishman and Baker's method. Section through *a*, the paraventricular nucleus ( $\times 130$ ); *b*, the choroid plexus ( $\times 142.5$ ); *c*, the subcommissural organ ( $\times 142.5$ ); *d*, the cortex of the cerebellum showing the Purkinje cells ( $\times 130$ ); *e*, the pineal gland ( $\times 15$ ).

particularly in the hypothalamic magnocellular neurosecretory nuclei, in the subcommissural organ, in the choroid plexus, in the Purkinje cells, and in the pineal gland. In the other parts of the brain, for example in the cortex of the cerebrum and cerebellum, and in some basal nuclei there was a rather diffuse reaction, and it was considerably weaker than that in the areas mentioned here.

The brains of 20 albino rats of both sexes were investigated by Fishman and Baker's ferric hydroxyquinoline method<sup>3</sup>, with slight modifications. Frozen sections 15–30  $\mu$  were cut with the Pearse freezing microtome, mounted on cover glasses, and fixed in chloral-formalin at 8°C, or at room temperature for 10 min to 2 h, incubated in substrate solution for 17 h at 8°C and then for 3–7 h at 37°C, placed in oxalate buffer for 15 min and finally in acid ferrocyanide solution. The specificity of localization was controlled by treating sections with 0.001 M saccharic acid.

The sites of the most intense reaction are shown in Fig. 1. Activity in the neurosecretory ganglia is cytoplasmic. In the subcommissural organ, strong activity is localized in the cytoplasm of the ependymal cells; the hypendyma is quite negative. The enzymatic activity is similarly localized in the ependyma in the choroid plexus. In this connexion it may be pointed out that the ependyma covering the walls of the cerebral ventricles shows only a very weak reaction or none. Activity in the Purkinje cells is cytoplasmic and it could be demonstrated also in the neurites and dendrites. The pineal gland exhibited a strong  $\beta$ -glucuronidase activity which seemed to be evenly distributed throughout the gland.

These observations suggest that the strongest  $\beta$ -glucuronidase activity is found in those parts of the brain which have, or are presumed to have, a secretory function. The only exception is the Purkinje cells, the physiological significance of which is problematic.

Precise evaluation of the functional role of  $\beta$ -glucuronidase in the brain must await further investigation. One might speculate that it is related to the synthesis of secretion in the 'secretory' regions which are rich in the enzyme. The hypothalamic-hypophyseal 'neurosecretory material' and the 'secretion' of the subcommissural organ are of protein character. It has also been suggested that the pineal gland secretes some factor of a protein nature. However, it is impossible to state on the basis of present knowledge whether  $\beta$ -glucuronidase is in fact involved in protein synthesis. The possible relationship between the activity of  $\beta$ -glucuronidase and liquor secretion in the choroid plexus is obscure.

### A Light-catalysed Reaction in the Aqueous Humour of the Eye

Kon and Watson<sup>1</sup> found that ascorbic acid in milk was destroyed by light and Hopkins<sup>2</sup> showed that this destruction was caused by the photocatalytic oxidation of ascorbic acid by riboflavin. Oxygen was necessary and peroxide was formed. In connexion with an examination of glutathione peroxidase of lens I became interested in the ascorbic acid of the aqueous humour as a possible source of hydrogen peroxide. In many mammals, including man, the level of ascorbic acid in the aqueous humour is about 1.0 mM, which is far higher than the level in serum<sup>3</sup>. Light freely penetrates through the aqueous humour whenever the eye is open, and Philpot and Pirie<sup>4</sup> found traces of riboflavin and/or flavinadenine dinucleotide in the aqueous humour of cattle eyes. It seemed possible, therefore, that a photocatalysed oxidation of ascorbic acid might take place in the eye *in vivo*, as it does in milk *in vitro*.

At the pH of the aqueous humour of the rabbit, which is near pH 7.6 (ref. 5), ascorbic acid is autoxidizable and small amounts of dehydroascorbic acid are present in both aqueous humour and lens. Traces of  $H_2O_2$  are also present in aqueous humour of cattle and rabbit (Pirie, to be published).

To examine the effect of light and of riboflavin on the oxidation of ascorbic acid in aqueous humour, this was removed from cattle eyes into a syringe, about 15 min after death, and kept in the dark on ice until used. Table 1 shows that exposure to ultra-violet light (max. 360 m $\mu$ ) at 0° or exposure to sunlight at 25° increases the rate of disappearance of ascorbic acid; at 25° the rate is about doubled in sunlight. Table 2 shows that addition of 0.125  $\mu$ g/ml. of riboflavin still further accelerates removal of ascorbic acid from aqueous humour in light but has no effect in the dark. The same is true of riboflavin phosphate

Table 1. EFFECT OF LIGHT ON ASCORBIC ACID OF CATTLE AQUEOUS HUMOUR

1. *Exposure to sunlight:* Cattle aqueous humour contained in a quartz cuvette was exposed to sunlight on an open windowledge. A sample of the same aqueous humour was put in a black-lined light-tight box also on the windowledge. Temp. 25°. Samples of 0.1 ml. were removed at intervals into spectrophotometer cups containing 1.0 ml. 0.05 M potassium phosphate pH 6.6, 1.6 ml. H<sub>2</sub>O + 0.3 ml. 2:6 dichlorophenol indophenol, made up so that 1.0 ml. = 0.1 mg ascorbic acid. The absorption at 600 mμ was measured before and immediately after addition of the sample of aqueous humour. The decrease in reading measures the ascorbic acid. The amount present can be read from a calibration curve made with known amounts of ascorbic acid and dye

Time (min)	Ascorbic acid $\mu\text{g/ml}$ . aqueous humour

80	112	90	—	74	—	95	76

and to a lesser extent of flavin adenine dinucleotide. To estimate ascorbic acid, aqueous humour was added directly to 2:6-dichlorophenol indophenol buffered at pH 6.6 in a spectrophotometer cup and the change in absorption at 600 mμ was measured. After this, H<sub>2</sub>O<sub>2</sub> was identified by adding peroxidase. If the method of titration with the dye in metaphosphoric acid had been used, peroxidase would have been inactivated. At pH 6.6, peroxidase and H<sub>2</sub>O<sub>2</sub> re-oxidize 2:6-dichlorophenol indophenol so that there is an increase in absorption at 600 mμ on addition of the enzyme<sup>6</sup>. Hydrogen peroxide was detectable in all samples but it did not accumulate, probably because it reacts with ascorbic acid.

At oxidation of ascorbic acid in the aqueous humour even in the dark is fairly rapid, but the results show that light accelerates it and that it is accelerated still more by addition of small amounts of riboflavin. It is possible that this reaction has physiological importance. Experiments (to be published in detail elsewhere) have shown that glutathione is oxidized during removal of ascorbic acid and that this oxidation is partly enzymatic, being catalysed by glutathione peroxidase of lens.

Oxidized glutathione can be re-reduced by NADPH<sub>2</sub> and glutathione reductase which is present in lens.

Kinoshita and Masurat<sup>7</sup> found that the supply of NADP in lens limited the oxidation of glucose by the pentose phosphate pathway and that, in certain circumstances, addition of oxidized glutathione stimulated oxidation of glucose. It is possible, therefore, that the whole

series of reactions, starting with uptake of oxygen by ascorbic acid in the aqueous humour, is advantageous to the lens. Zeller<sup>8</sup> found that lens contains only traces of catalase so that nearly all H<sub>2</sub>O<sub>2</sub> formed may be available to glutathione peroxidase.

The effect of light on the retina is so fundamental for vision that attention has been focused on this and we have largely overlooked the fact that most tissues and fluids of the eye are bathed in light. Oxidation of ascorbic acid in aqueous humour is perhaps simply one of a group of light-catalysed reactions in the eye.

### Effect of Solvated Ions on the Activity of Esterases in the Housefly

A NUMBER of electrolytes, which are in common use in the fractionation of proteins, have been studied for their effect on choline- and ali-esterase of the housefly. The substrates were acetylcholine and ethylbutyrate, respectively. Enzyme activity was measured by a pH-titrimetric method using barbitone-HCl (pH 7) as buffer.

The results, illustrated in Fig. 1a and b, show that all salts that were tested activated acetylcholinesterase and inhibited the ali-esterase in more or less the same order. The order of the effect of the salts corresponds to the order of their energy of hydration. Heats of hydration<sup>1</sup> are 490, 410, and 114 kcal/g-ion for Mg<sup>2+</sup>, Ca<sup>2+</sup>, and Na<sup>+</sup>, respectively, while the lyotropic number<sup>2</sup> for SO<sub>4</sub><sup>2-</sup> is 2 and that for Cl<sup>-</sup> is 10, indicating that the former has a higher affinity for water than the latter. However, MgSO<sub>4</sub> may have a lower energy of hydration than MgCl<sub>2</sub> due to its low degree of dissociation<sup>3</sup>.

It is possible, therefore, that the effect of electrolytes on esterases is related to the solvation of ions, the consequences of which can be discussed as follows.

Proteins have a high affinity for water, with which they bind possibly through hydrogen bonds. Water of solvation confers a high degree of stability on protein colloids by blocking the polar groups on the surfaces of the molecules and thus preventing cohesion. Water of solvation must also exist in equilibrium with the free water, the capture of a large part of which due to ion hydration will reduce the thickness of the water shell around the protein molecule, and this intensifies the electrostatic field on the surface of the enzyme leading to cohesion. Thus, with the aliesterase, the attraction between enzyme particles seems greater than between enzyme and the ethylbutyrate molecule. However, in the case of cholinesterase which possesses an anionic site in its active centre, ion hydration should result in increase in activity in the presence of a very polar substrate such as acetylcholine. This is supported by the fact that MgCl<sub>2</sub> at 0.1 M reduced the activity of acetylcholinesterase towards the dimethyl amino analogue of acetylcholine, which is non-polar by 25 per cent.

The inhibition of cholinesterase by large concentrations of salts of high hydration energy can be explained on the basis of polarity, but may throw light on another more important aspect of the water of solvation which could be largely responsible for the inhibition of the aliesterase.

Fig. 1. Effect of electrolytes on the activity of (a) cholinesterase; (b) alkaline phosphatase. ●, CaCl<sub>2</sub>; ○, MgCl<sub>2</sub>; ▲, MgSO<sub>4</sub>; ×, Na<sub>2</sub>SO<sub>4</sub>; — · —, NaCl

Esterase activity, like that of many enzymes, is influenced by the concentration of the substrates, which are the ester and water. Relatively little attention has been given to the state in which water exists, in view of the fact that enzyme reactions take place in aqueous solutions. However, ion hydration will lead to the existence of large quantities of water in an unavailable ion-bound form and the concentration of enzyme-bound and free water will be lowered. Since enzyme reactions are adsorption reactions, it is not unnatural to regard the water of solvation which is already adsorbed on the surface of the molecule as the one directly used for hydrolysis, the partial removal of which will affect enzyme activity. This suggests that during hydrolysis the enzyme particle is involved in a continuous process of dehydration and solvation.

## Reaction of Pyridine Nucleotides with 2,4-Dinitrophenylhydrazine

WHILE attempting to isolate and identify pyridine nucleotide-dependent and enzymatically-formed aldehydes and  $\alpha$ -keto acids as their 2,4-dinitrophenylhydrazone derivatives, it was noted that derivatives were formed which, when chromatographed on paper, were unlike known standards and gave blue colours when sprayed with alcoholic KOH. The reaction mixture in which this phenomenon was first observed was a control tube that contained: *tris*-HCl buffer, pH 8.5, 1,500  $\mu$ moles; nicotinamide-adenine-dinucleotide (NAD), 10.0  $\mu$ moles; and crude cell-free extract containing 1.2 mg protein in a total volume of 3.8 ml. The incubation was terminated by the addition of an equal volume of saturated 2,4-dinitrophenylhydrazine (DNPH) in 2 N HCl. The reaction mixture was centrifuged to remove precipitated protein and the supernatant fluid decanted into a clean test-tube and incubated overnight at 37° C. Further investigations revealed that the flocculent precipitate which formed was due to a reaction between NAD and DNPH. This product was purified by the usual extraction procedure including initial extraction with ethyl acetate to remove unreacted DNPH, neutral and acidic hydrazones; the latter were re-extracted into 10 per cent sodium carbonate, leaving unreacted DNPH and neutral hydrazones behind in the organic phase; the carbonate layer was acidified at 4° C and re-extracted with ethyl acetate. The ethyl acetate layer was evaporated and aliquots were used for spotting on to paper chromatograms.

In the light of the results obtained with NAD, the investigation was extended to nicotinamide-adenine-dinucleotide-phosphate (NADP) and the reduced forms, NADH and NADPH. These latter compounds also gave additional products when treated with DNPH. To each of

Fig. 1. Absorption spectra of compounds formed between 2,4-dinitrophenylhydrazine and NADH or NADPH. See text for details.

Fig. 2. Absorption spectra of compounds formed between 2,4-dinitrophenylhydrazine and NAD, NADP, and ribose. See text for details

four tubes, containing 300–500  $\mu$ moles of one of the pyridine nucleotides were added 50 ml. of DNPH solution. While tubes containing NADH and NADPH became cloudy almost immediately, those containing the oxidized forms of the pyridine nucleotides formed precipitates slowly. After 16 h at 37° C, large quantities of flocculent material were evident in the tubes containing NADH and NADPH, while the tubes containing the oxidized forms contained considerably less precipitated material. The addition compounds thus formed were only slightly soluble in 1 N HCl but were quite soluble in water. They were also soluble in ethyl acetate, ether, pyridine and acetone.

Samples were analysed spectrophotometrically in a Cary Model 14 recording spectrophotometer by dissolving a small amount of precipitate in alkaline solution (1 part 2 N NaOH and 1.5 parts 10 per cent  $\text{Na}_2\text{CO}_3$ ). Fig. 1 shows that either NADH or NADPH forms two additional compounds with distinct optical properties. These two addition compounds settled in the tube as two distinct layers of precipitate; a denser orange compound below and a less dense, red compound on top of it. Samples were removed for spectral analysis by carefully collecting them from the separate layers with a capillary pipette. Efforts to separate the two additional compounds by centrifugation were unsuccessful. As shown in Fig. 1, the two compounds had maximal absorptions in the 410–420  $\text{m}\mu$  and 550–560  $\text{m}\mu$  regions, respectively. The small peaks and shoulders probably represent contamination of one compound with the other. Absorption spectra were obtained within 10 min after placing the precipitates in alkali, since it was noted that the absorbance of the 550–560  $\text{m}\mu$  peak would decrease, while the 410–420  $\text{m}\mu$  peak would increase with time.

Samples for spectral analysis of NAD and NADP additional compounds were obtained in the way described for their reduced forms. These precipitates, however, appeared homogeneous. The spectra of materials collected from either tops or the bottoms of the precipitate layers were identical, as shown in Fig. 2. Included in Fig. 2 for comparative purposes is the absorption spectrum of authentic ribose osazone. It can be seen that, with one exception, the absorption in the 410–420  $\text{m}\mu$

region, the addition compounds of the pyridine nucleotides resemble the sugar osazone.

Treatment of pyridine nucleotides with strong acid will hydrolyse the pyrophosphate moiety<sup>1</sup>. Complete acid hydrolysis of NAD yields adenine, nicotinamide, ribose and phosphoric acid in the ratio of 1 : 1 : 2 : 2 (refs. 2, 3). The action of strong acid on NADP results in the formation of the same products with an additional phosphate group<sup>4</sup>. Thus, it might be expected that the addition compounds described herein are 'ribose-like'. It is to be noted that the most significant difference is the solubility of these products in water as compared to the ribose osazone, which is insoluble.

Reduced pyridine nucleotides are very unstable in strong acid. Anderson and Berkelhammer<sup>5</sup> showed that the nicotinamide moiety adds water to form a compound that reacts with both phenylhydrazine and dinitrophenylhydrazine. They postulate that these reactions represent an acid-catalysed ring opening at the 6-position to give the amino aldehyde. We suggest that it is the amino aldehyde-ribose-DNPH compound in our mixtures which absorbs maximally in the 410–420  $\text{m}\mu$  range.

This report is intended to clarify difficulties which may arise from attempts to isolate aldehydes or  $\alpha$ -keto acids as their 2,4-dinitrophenylhydrazone derivatives from mixtures containing pyridine nucleotides. It originated from work supported by grants from the U.S. Public Health Service (A1-03868-03) and the National Science Foundation (GB 2020). One of us (H. C. R.) holds a research career development award (5-K3-A1-6928-02) from the National Institutes of Health.

## PHYSIOLOGY

### Long-term Preservation of Bone Marrow

PRESERVATION of the functional integrity of cells stored at low temperatures has become routinely successful. Current efforts in cryobiology centre around improvement of the techniques, assessment of the physico-chemical alteration of cells by low temperatures, and evaluation of the length of time for which frozen cells will maintain their functional capacity. It has been reported, for example, that bull spermatozoa can be stored successfully at  $-79^\circ\text{C}$  for at least 7 years<sup>1</sup>, and that some human cell lines remain viable for 33 months<sup>2</sup>. During the course of experiments with various techniques for freezing and storing mouse bone marrow<sup>3</sup>, we froze a number of samples to be tested at long intervals. The present interim report describes the results of these experiments.

The reproductive integrity of mouse bone marrow after preservation at low temperatures was measured by the ability of the infused cells to promote recovery of lethally X-irradiated mice. The procedures used were the same as previously reported<sup>3</sup>, with the exception that the irradiated recipient was the ( $\text{C3H} \times \text{C57BL}$ ) $\text{F}_1$  mouse rather than the ( $\text{C57BL} \times 101$ ) $\text{F}_1$ . The preserved marrow was from the ( $\text{C57BL} \times 101$ ) $\text{F}_1$  hybrid, and it would have been desirable to use the same type hybrid, but these were not readily available. The C3H and 101 strains, however, possess the same major histocompatibility antigens.

To present a complete picture of the data obtained so far, Table 1 includes results of some experiments (section A) previously reported<sup>3</sup>. From section A of Table 1, it is seen that marrow stored at  $-30^{\circ}\text{C}$  for 25 weeks was ineffective in promoting survival of lethally irradiated mice. By ineffective we mean that in the injected inoculum of  $10^6$  nucleated cells there were not enough viable cells to prevent death of any of the recipients.

Table 1. LONG-TERM STORAGE OF FROZEN MOUSE BONE MARROW. X-RAY EXPOSURE WAS 900 OR 950 R. EACH MOUSE RECEIVED  $10^6$  MARROW CELLS INTRAVENOUSLY IN 0.5 ML. SECTION A FROM DATA OF BENDER, TRAN AND SMITH (REF. 3)

	No. mice	Storage temp. ( $^{\circ}\text{C}$ )	Storage time	Per cent 30-day survival
A	25	-30	1 hour	83
	25	-30	4 weeks	57
	25	-30	25 weeks	0
	25	-70	1 hour	80
	25	-70	22 weeks	80
	25	-196	1 hour	68
	25	-196	4 weeks	80
	25	-196	25 weeks	72
	292			0 (X-ray control)
B	29	-196	29 months	79
	13			0 (X-ray control)
	16	-196	57 months	88
	10			0 (X-ray control)

In a solid  $\text{CO}_2$  refrigerator ( $-70^{\circ}\text{C}$ ), effective cells were present after 22 weeks' storage. It was not possible to test cells stored at  $-70^{\circ}\text{C}$  beyond 22 weeks because of accidental thawing of the refrigerator. At liquid nitrogen temperature ( $-196^{\circ}\text{C}$ ), effective cells were present after 25 weeks' storage. Section B of Table 1 shows the results of the most recent tests of marrow stored at  $-196^{\circ}\text{C}$  for 29 and 57 months. It is apparent that some cells retained their reproductive capacity for almost 5 years at  $-196^{\circ}\text{C}$ . On thawing, the 57-month preparation contained a slight amount of white fibrous material, and the cell concentration was reduced by about 50 per cent. In part, this reduction could have resulted from a moderate degree of cell clumping that was observed microscopically. Eosin uptake of this preparation was 58 per cent. Biennial testing of the stored marrow is proposed.

### Antigenic Components in Human Pituitary Follicle-stimulating Hormone Preparations of Various Purities

THE production of an antiserum to a preparation of human pituitary follicle-stimulating hormone (HP-FSH) which had been fractionated by electrophoresis on starch gel (SG4) has been described previously<sup>1,2</sup>. Immuno-electrophoresis of various HP-FSH preparations with this antiserum showed the presence of two precipitin lines. These two lines obtained with antigens of 1 mg/ml. solutions (w/v) were now investigated by comparing three HP-FSH preparations of different purity, CM 1 (ref. 3), CP 1 (ref. 3) and SG 4 (Fig. 1, A, B, C), and by absorbing the antiserum with various proteins.

Fig. 1. Immuno-electrophoretic pattern of: A, CM 1 (crude human pituitary FSH); B, CP 1 (purified human pituitary FSH); C and D, SG 4 (highly purified human pituitary FSH); E, human pituitary LH. A, B, C and E developed by antiserum to SG 4. D developed by antiserum to human serum albumin. The antigens were applied in 1 mg/ml. solutions. Left—contact prints; right—schematic drawings

Fig. 2. Schematic pattern of human pituitary FSH showing the agar sections I-V which were eluted after electrophoresis for injecting into mice

The anodic precipitin line was probably due to the presence of albumin or a closely related protein in the HP-FSH preparations. It appeared with all preparations in the position of human serum albumin after electrophoresis and was not seen after the antiserum had been absorbed with normal human serum or human serum albumin. Moreover, an antiserum to human albumin gave a precipitin line in the same position when it was used instead of the anti-HP-FSH serum (Fig. 1D). When the HP-FSH antigens were used in higher dilutions (500  $\mu\text{g}/\text{ml}$ .) the albumin line was removed while the second line remained. The appearance of this second precipitin line varied with the purity of the HP-FSH preparations. The line of the crude material (CM 1) and of the purified material (CP 1) showed a cathodic tail which was not present when highly purified HP-FSH (SG 4) was applied. This cathodic end of the line occurred in the  $\gamma$ -globulin position and was removed after the antiserum had been absorbed by a preparation of human pituitary luteinizing hormone (HP-LH) which had been fractionated by chromatography on DEAE-cellulose<sup>4</sup>. HP-LH, on the other hand, gave a precipitin line in the  $\gamma$ -globulin position (Fig. 1E).

Evidence in favour of the anodic part of this line (in  $\alpha$ - $\beta$ -globulin position) being due to HP-FSH was obtained by eluting sections of the agar gel marked I-V in Fig. 2 after electrophoresis of purified HP-FSH (CP 1). Most activity was detected by the ovarian augmentation assay for FSH in the region of this part of the band (Table 1).

It appears, therefore, that all three HP-FSH preparations probably contained a contaminating protein related

Table 1. RESULTS OF BIO-ASSAYS WITH ELUATES OF AGAR SECTIONS

No. animals	Section	Mean ovarian wt. (mg) with 95% confidence limits
6	I	8.4 (5.7-12.8)
6	II	16.5 (11.3-24.1)
6	III	8.9 (6.1-13.0)
6	IV	4.2 (2.9-6.1)
6	V	3.6 (2.5-5.3)

to human serum albumin and that the less-purified preparations contained another contaminant closely related to HP-LH. The HP-LH is largely removed in the highly purified HP-FSH as has previously been shown by bioassays<sup>1</sup>. The immuno-electrophoretic pattern can thus be used as a rough indication of the purity of a HP-FSH preparation.

The presence of contaminants would probably interfere with the haemagglutination assay of FSH but it is possible to improve the specificity of the method by suitable absorption.

This work was supported by a grant from the Medical Research Council.

## PHARMACOLOGY

### Effects of Noradrenaline and Isoprenaline on the Permeability of Depolarized Intestinal Smooth Muscle to Inorganic Ions

It has recently been shown<sup>1,2</sup> that stimulation of the intrinsic inhibitory nerves of the guinea-pig taenia coli can cause a transient increase in the membrane potential of the smooth muscle cells. The magnitude of the hyperpolarization was found to vary with the external potassium concentration in a way which suggested that the transmitter, almost certainly largely noradrenaline, acts by increasing the permeability of the membrane to potassium ions. According to another hypothesis<sup>3,4</sup>, adrenaline, and presumably noradrenaline, can hyperpolarize the membrane by stimulating electrogenic extrusion of sodium from the cells.

The effect of noradrenaline on the permeability of the smooth muscle membrane to sodium and potassium ions has been further investigated in the present work. We have also attempted to identify the receptors involved in the permeability change since little is known of the relative functions in intestinal muscle of the two types of catecholamine receptor (usually termed  $\alpha$  and  $\beta$  following Ahlquist<sup>5</sup>) which have been demonstrated in many tissues. A comparison was therefore made of the actions of noradrenaline and isoprenaline, which were selected as representative catecholamines having predominantly  $\alpha$ - and  $\beta$ -activating properties, respectively.

The techniques used were essentially similar to those developed during an earlier investigation of the actions of carbachol on permeability<sup>6</sup>. As before, strips of taenia coli mounted on stainless-steel holders were bathed throughout in fluid containing sufficient potassium sulphate to depolarize the cells. Radioisotopes could then be used to examine the exchange of ions between tissue and bathing fluid without the complication of changes in ion movement secondary to alterations in membrane potential.

Fig. 1 illustrates the effect of  $3 \times 10^{-7}$  g/ml. *l*-noradrenaline bitartrate on the efflux of tracer potassium from muscle equilibrated at 20° C in a bathing fluid containing 235 mM K<sup>+</sup> and 6.5 mM Na<sup>+</sup>. An increase in the rate of loss was consistently observed, whereas the same concentration of *dl*-isoprenaline sulphate was without effect. Other experiments in this series showed that this concentration of noradrenaline also enhanced inward movement of tracer potassium, isoprenaline again having little action. These results confirm that noradrenaline

Fig. 1. Effect of *l*-noradrenaline bitartrate ( $3 \times 10^{-7}$  g/ml.) and *dl*-isoprenaline sulphate ( $3 \times 10^{-7}$  g/ml.) on the rate of loss of tracer potassium from taenia coli bathed in potassium-rich fluid. ■, Noradrenaline,  $3 \times 10^{-7}$  g/ml.; ●, isoprenaline,  $3 \times 10^{-7}$  g/ml.

can increase the permeability of the membrane to potassium ions.

Experiments of a more preliminary nature have also been made to find whether the permeability increase extends to sodium ions. These measurements were made at 10° C in a fluid containing 190 mM K<sup>+</sup> and 52 mM Na<sup>+</sup>. The lower temperature and higher sodium concentration were adopted in an attempt to overcome earlier difficulties in the analysis of tracer sodium flux at 20° C (ref. 6). It was thought necessary first to demonstrate that a substance considered to increase sodium permeability did, in fact, alter sodium uptake under these conditions. Carbachol was chosen for this purpose, and a comparison was made of the effects on sodium exchange of concentrations of carbachol and noradrenaline ( $5 \times 10^{-7}$  and  $3 \times 10^{-7}$  g/ml., respectively) shown to cause a similar increase in potassium uptake. It was found that whereas carbachol did produce a significant increase in sodium uptake, noradrenaline was without effect. The actions on sodium efflux have not yet been determined.

Since noradrenaline produced a change in permeability to potassium ions, whereas isoprenaline was ineffective, it seems likely that this effect is mediated through the  $\alpha$ -receptors. This conclusion was supported by experiments with adrenergic blocking agents (Fig. 2). The  $\alpha$ -blocking agent phentolamine hydrochloride ( $10^{-7}$  g/ml.) was found to greatly reduce the effect of noradrenaline ( $3 \times 10^{-7}$  g/ml.) on potassium exchange. Moreover, the  $\beta$ -blocking agent pronethalol ( $10^{-7}$  g/ml.) was without effect.

It is interesting in relation to these findings that catecholamines can reduce the tension that is developed

Fig. 2. Comparison of the effects of an  $\alpha$ -antagonist (phentolamine hydrochloride,  $10^{-7}$  g/ml.) and a  $\beta$ -antagonist (pronethalol,  $10^{-7}$  g/ml.) on the increase in the rate of loss of tracer potassium due to noradrenaline ( $3 \times 10^{-7}$  g/ml.). The antagonists were present in the bathing fluid from 5 min after removal of muscles from the load solution.

by depolarized smooth muscle in the presence of calcium ions<sup>7</sup>. We have found that, in the depolarized taenia, isoprenaline was much more active in this respect than noradrenaline, indicating that the effect was mediated through  $\beta$ -receptors. This was confirmed by the observation that pronethalol, at the same concentration as in the experiment illustrated in Fig. 2, strongly antagonized this action of noradrenaline.

Summarizing, our results suggest that noradrenaline can act through the  $\alpha$ -receptors to increase the permeability of the membrane to potassium, but not to sodium, ions. Since under physiological conditions the membrane potential is most probably below the potassium equilibrium potential, an increase in potassium permeability would tend to hyperpolarize the membrane and reduce the frequency of spontaneous action potentials. These  $\alpha$ -mediated effects would, in themselves, serve to account for many features of the relaxation of intestinal smooth muscle in response to catecholamines. However, under conditions where the membrane potential had been abolished, activation of the  $\beta$ -receptors was also found to cause relaxation. There is, as yet, little to suggest what mechanism underlies this response, although it seems possible that a change in the availability of metabolic energy (cf. refs. 8 and 9) might be involved. If this mechanism operates under physiological conditions, then both  $\alpha$ - and  $\beta$ -receptors would contribute to the relaxation induced by catecholamines; this conclusion is supported by other evidence<sup>10,11</sup>.

### Neuropathological Effects of Dosing Dogs with Isonicotinic Hydrazide and with its Methanesulphonate Derivative

THE neuropathological effects of dosing dogs over a prolonged period with some monoamine oxidase inhibitors have already been described by us<sup>1</sup>. Two of the drugs, phenyl-iso-propyl hydrazine ('JB 516' or 'Catron') and tetra-hydronaphthyl hydrazine, produced strikingly focal bilateral degeneration of the inferior olives. Phenelzine ('Nardil') and indanyl carbethoxy hydrazine resulted in oedema and disintegration of sub-cortical myelin in the cerebrum, accompanied by microglial proliferation. It was suggested that perhaps a contributory cause of both types of lesion might be ascribed to elevated levels of brain serotonin.

Opportunity has since arisen to examine the effects of dosing dogs over a prolonged period with two hydrazides, which are not monoamine oxidase inhibitors, and this has thrown light on the pathogenesis of the cerebral oedema seen in the previous experiments with phenelzine and indanyl carbethoxy hydrazine. The two compounds in question are isonicotinic hydrazide (isoniazid) and its methanesulphonate derivative. Oral administration of these drugs was carried out for periods of up to 6 months

Fig. 1. Section of sub-cortical white matter from dog (No. 285) dosed with 'Isoniazid' (15 mg/kg/day) showing clefts and spaces, disintegration of myelin, glial activation and capillary hyperplasia. Tissue fixed in formal saline, embedded in paraffin and section stained with haematoxylin and eosin

Fig. 2. Section of sub-cortical myelin from control dog. Fixation, embedding, staining and magnification the same as for Fig. 1

using the method described by us. After preliminary trials, the dose-levels finally used were: isoniazid 15 and 5 mg/kg/day and for its methanesulphonate derivative 20, 10 and 6 mg/kg/day.

The neuropathological effects of the two compounds appear to be similar. In both, at the higher dose-levels, there is separation of fibres in certain areas of the sub-cortical myelin. Clefts or spaces occur, accompanied by activation of microglia and hypertrophy of astrocytes (Figs. 1 and 2). There is pallor of affected regions, with variable staining of myelin and occasional ballooning of the sheath suggesting its disintegration. Frozen sections show the presence of only a few lipid-filled phagocytes around vessels. The axons remain intact, and the majority of cortical neurones appear healthy although there is microcavitation of the ground substance.

The neuropathological effects of dosing dogs with 15 mg/kg/day of isoniazid are about the same as those of dosing with 20 mg/kg/day of its methanesulphonate derivative, which on this evidence would appear to be slightly less toxic than isoniazid. In two dogs dosed with the methanesulphonate at 10 mg/kg/day there was, however, severe laminar necrosis of the cerebral cortex, a change not seen with isoniazid.

The effect of isoniazid and its methanosulphonate derivative on the brain of the dog appears to be the production of oedema in the cerebral white matter, leading to loss of myelin, and accompanied by glial proliferation. These changes are very similar both morphologically and in distribution to those produced previously with phenelzine and indanyl carbethoxy hydrazine, but as isoniazid and its methanosulphonate derivative are not monoamine oxidase inhibitors, it would suggest that the changes in the myelin produced by all four drugs are not due to monoamine oxidase inhibition. The histological changes are reminiscent of those induced in rats by administration of triethyl tin compounds by Magee *et al.*<sup>2</sup>, in which there is widespread oedema of myelin, with spaces between the fibres, but axons and myelin are intact; later work has shown that the oedema accumulates in large clefts within myelin sheaths<sup>3</sup>.

## HAEMATOLOGY

### Relationship between Activity of Pyruvate Kinase and Age of the Normal Human Erythrocyte

MATURE erythrocytes of human beings derive energy chiefly through anaerobic glycolysis. Pyruvate kinase catalyses a key<sup>1,2</sup>, adenosine triphosphate-generating glycolytic reaction. We have examined the relationship between the activity of pyruvate kinase and the age of the normal human red cell.

Freshly drawn venous blood, anticoagulated with heparin, was obtained from each of six normal adult males. A modification<sup>3</sup> of a method of serial centrifugation<sup>4</sup> was used to separate erythrocytes into fractions containing relatively young and relatively old packed red cells. Reticulocyte, erythrocyte, leucocyte, and platelet counts of these fractions were determined. Haemolysates were prepared by freezing and thawing 1 ml. of each fraction of red cells three times and by subsequent addition of distilled water. Activities of both pyruvate kinase and glucose-6-phosphate dehydrogenase (G-6-PD) were measured. Available evidence indicates that the activity of G-6-PD in the normal human red cell decreases as the cell ages *in vivo*<sup>5,6</sup>.

Results are shown in Table 1. Reticulocyte counts and activities of G-6-PD provide evidence that centrifugation effected significant separation of young and old cells. The mean activity of pyruvate kinase in haemolysates of relatively old red cells proved 45 per cent less than that in haemolysates of relatively young red cells. The mean platelet count of fractions of relatively young red cells (78,000/mm<sup>3</sup>) was less than that of fractions of relatively old cells (103,000/mm<sup>3</sup>); contamination by platelets, therefore, does not account for the difference detected between the mean activities of pyruvate kinase in haemolysates of young and old red cells. The mean leucocyte count of fractions containing relatively young red cells was 840/mm<sup>3</sup> and that of fractions containing relatively old cells was 340/mm<sup>3</sup>. We investigated the activity of pyruvate kinase in lysates of leucocytes purified by the method of Fallon *et al.*<sup>11</sup>. These investigations indicated that less than 6 per cent of the activity of pyruvate kinase in any of the haemolysates examined (Table 1) was
